1679. Re: Tayloe detector again

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-19 15:15:26 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <ajr22f$1cso11$1@ID-61331.news.dfncis.de>
Source record: 42142

I have become a big supporter of the Tayloe method, see my receiver here: http://www.hanssummers.com/radio/polyphase/index.htm, but no time yet for drawing circuit diagrams I'm afraid.

I built an 8-stage polyphase network using 0.1% resistors, and matched the capacitors also to within 0.1% by switching them into a 555 oscillator circuit and measuring the frequency. Unlike many polyphase networks which have same-value resistors, or capacitors (and vary the other), I vary both resistor and capacitor values from one column to the next in accordance with a 1995 QEX article. This eliminates losses in the polyphase network which can otherwise be troublesome. I measured it and it really is lossless it's not just theory.

This receiver is very impressive. I am unable to measure the opposite sideband with my existing primitive measuring equipment, which can only go down to -40dB. I have not yet made any balance adjustments to the polyphase network. Because it is direct conversion I don't get any birdies or image rejection problems.

I recently had my first ever QSO using this receiver and my one-valve 80m transmitter (http://www.hanssummers.com/radio/cwtx/index.htm), homebrew ATU (http://www.hanssummers.com/radio/atu/atu.htm) and frequency counter (http://www.hanssummers.com/electronics/equipment/radiofreqcounter/intro.htm). I have now had 12 contacts with it on 80m, most within the UK but also an SM, F and PA.

|Yeah, international standardisation of measurements, currencies, company
|accounts, languages, is a matter of economics, saving of labour and a
|reduction of friction.

For example, we both speak English but haven't standardized on how to
spell standardise <G>.

There is one de facto monetary standard however, the US greenback.
Regardless of how a people might hate the US, they still love our
money. Funny how that works. I think that's the "reduction of
friction" Reg speaks of.

Hi all,

We make TFT monitors at work, and I can tell you that they can potentially produce more RFI than CRT units. In common with most digital systems this RFI is broadband.

That said, here in Europe we have pretty tough EMI lgislation, all electronic devices sold for use in the EEC must conform to these directives and be marked (CE), so steps are taken to reduce EMI to acceptable levels.

The video cable is still the biggest source of RFI. Many units come with a cheap nasty cable. Buy a good VGA cable and replace the one that shipped with your unit. Check that good earth contact is made throughout the computer unit's case.

1682. SWL antenna help sought. Please.

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-19 18:56:23 UTC
From: secret_studio@charter.net
Message-ID: <3d613d3d.10339277@news.charter.net>
Source record: 42145

I am a blind SWL who faces some pretty tough reception challenges:

1. My home QTH is a one-story bungalow, located on the north side of a high hill. The small lot is surrounded on all four sides by A.C. power lines, in addition to a line underground. The house also sits in the lobe of our local A.M. broadcast station (5kW at 920 kHz).
2. Being blind, I'm uncomfortable with trying to erect an outdoor antenna. Furthermore, my last two random-wire antennas were vandalized by neighbors (who ignorantly blamed the longwire for causing interference on their cable T.V. signals!) I do have a 30' (a bit less than 10 m) expanse of attic in which to erect a wire antenna, oriented N <-->S.
3. I'm using an aging IC-751A xceiver and an equally old Sangean '803, although I plan to replace the Icom (which needs service) with a recently-acquired NRD-525.

Any suggestions would be most welcome. Hey Elmer! Where are you/?

Roy Lewallen <w7el@eznec.com> writes:

> For the record, we also have 8 pints to a gallon. But our pints are 16
> ounces instead of 20. Our ounces are the same size as yours, so the
> net result is that our pints, quarts, and gallons are 4/5 the size of
> the imperial versions. Here, a "pint's a pound, the world around"
> (pint of water, that is). There, a "pint of water weighs a pound and a
> quarter".

The ounces are not the same either. The imperial fluid ounce is
slightly smaller than the U.S. one.

The U.S. gallon is defined as exactly 231 inï¿½, and the fluid ounce is
1/128 of that, which works out to 29.57 cmï¿½.

The imperial gallon was originally defined as the volume of 10 lb of
water at a certain temperature and atmospheric pressure, and more
recently it was redefined as exactly 4.546 09 dmï¿½. The fluid ounce is
1/160 of this, which works out to 28.41 cmï¿½.

So, the U.S. fluid ounce is 4% bigger than imperial; from gill to
gallon the U.S. version is 17% (not 20%) smaller than imperial.

Source record: 42049

I just installed a one watt, 33 volt zener in a circuit that requires the bias to be 15 ma to handle the load variation. Thirty three volts at .015 amp computes to an RCH under 1/2 watt. So is it normal for a one watt component to run so hot that I cannot hold my finger on the thing? Seems to hold up for the several minutes that I have run it at one stretch.

Robert -

The photos are terrible, if you can't take a photos with an electronic
camera -
please don't bother posting them (very hard on my eyes)

The 4 crystals with 4.0 MHz compose the IF filter (common homebrew approach)

Small Wonder Labs and QST designs about 10 years ago liked to use 4.0 MHz
for an IF

Dave had a number of SSB and CW transceiver kits through the years
E-mail Dave, with a good photograph
http://www.smallwonderlabs.com/

Another possibility would be the classic '40-40' transceiver by the New
England QRP club. This design was subsequently published in the November '94
issue of QST and serves as a centerpiece for the ARRL's anthology, 'QRP
Power".

Robert -

Well my eyes hurt bad enough that I went to my library and pulled down the
QRP Power reference that I mentioned earlier.

Yes, your blurry photo does appear to be the Single Board Superhet QRP
Transceiver for 40 or 30 meters (depending upon component values)

Dave Benson, NN1G (and owner of Small Wonder Labs) was the author of the
November 1994 QST article.
You can also find the article in the QRP Power book or the April 1994 Issue
of "72" the New England QRP Club newsletter.

Q6 is a 2N3553 final PA RF transistor (MRF-237 can be substituted)
Drive adjustment is set by R2
Power output 1 - 2 watts.

Your voltage regulator IC is U2, 78L08 (8 volts)

You can e-mail Dave Benson, NN1G at Small Wonder Labs for any specific
questions you may have.
Chapter 3 of QRP Power has the original QST article as well as follow-up
articles and customizations

100 degrees C junction temperature should not cause it to fail very
quickly, but lower temperature is better. I have soldered little
brass shim stock wings on the elbows of the bent leads of hot diodes
to give them more surface area to get rid of heat. I think one watt
diodes only have that full rating if mounted very close to a circuit
board with very large solder pads (a square inch, each, or so) on both
sides of the board to act as heat sinks. The one watt spec usually
includes a lead temperature limit very close to the diode body. It is
really a pretty optimistic continuous rating for long life and
reliability.

Roy,

Nice to have the author respond and thanks. Insertion loss on those
meters (hm-102) is quite low. If power levels are kept at/less than 500

W, do you think that local heating would be of a level likely to significantly alter diode Is. That is, if my meter is housebound and used at/below these power levels can I take the easy way out and ignore temp variation?? Thanks again.

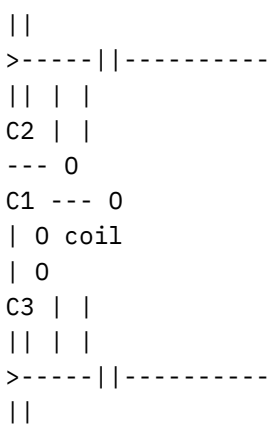
Gary

1694. NMR coil detunes

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-20 11:19:23 UTC
From: Martin Kavec <martin.kavec@uku.fi>
Message-ID: <ajt8k2jau1@luotsi.uku.fi>
Source record: 42057
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,sci.techniques.mag-resonance

Hello everybody,

I would like to ask you for explanation and possible solution for a p
roblem I face.
I made following brand new NMR coil:



This is a simple surface coil (loop of wire, since I post to a groups
where they might not be aware of this term) 3 cm diameter, made of round
copper wire (1.3mm diameter) and the capacitors are high quality nonma
gnetic trimmers made by Voltronics. The coil is powered by coaxial
cable (MIL-17/RG400) 50Ohm cable. The tune frequency is 200MHz. The coil
tunes fine and matches fine (though I don't know exactly on res
onance resistance).
The problem is that the coil detunes as soon as I move the coaxial cable.
Not a problem but a seek for information: I read that additional cap
acitor parallel to the coil wire, attached directly on the wire improves th
e coil homogeneity and the quality. How can I calculate the value of
such a capacitor.

Thank you and I appreciate any kind of help.

Martin Kavec

==========
For Ham Radio a very good book for starters is an ARRL (American Radio Relay
League) publication ;
'Now you are talking !' 445 pages , ISBN: 0-87259-597-8.
It is not only an excellent introduction to ham radio but also a course book
for the US Ham Radio
Technician License . I am sure you will be able to find it with the
assistance of a local Ham
through a local radio club ,or from a library in your country.

Good Luck and welcome on board

Frank gm0csz.kn6wh@ntlworld based in Scotland.

Many thanks for the ideas. I am putting together a battery powered
receiver to use as a sniffer.
I doubt that the signals are coming from a TV set as the signals are
much too stable in frequency.
I am in a rural area. Most close neighbor is about 300 meters away.
The signals have taken not to be on all of the time. That
complicates finding the source.
Thanks again for the ideas. I will let you know what I find. 73

Martin,

Is the drive 'balanced', or does the other side of C3 go to the coax
braid? I would think you'd need to add a balun to stop 'antenna
current' flowing on the braid and making it part of the resonance problem.

If a tight coil of a few turns of the coax near the coil reduces the
detuning effect, that is probably the problem. You could go the sleve
bead choke way as well, but a real VHF balun seems more likely to work well.

You could try making the coil itself the balun.

I have a working Heathkit C-3 that I don't need, and want to sell. It is gray in color, in good shape with the usual use/storage wear, but a couple of the knobs have hairline cracks that could probably be fixed with cement (or just replaced). It is also missing the 1629 eye tube, although if an offer was good, I might be convinced to part with one of mine. I pulled a 1629 from another radio and tested it with the tube installed, and it correctly read all the capacitors and resistors I tested. I've also got a non-orignal manual (printed off of the BAMA) that goes with it.

I don't really know what this is worth, so I'll entertain all genuine offers. If interested, please e-mail me directly.

Hi,

Please excuse me if I've read you wrong but you mention scanners and ham radio together, so it may be that your tastes include public service and utility communications as well as ham radio. In which case, along with any ARRL publications that are recommended you may find such monthly publications as 'Monitoring Times' and 'Popular Communications' to your liking - at least at first.

ARRL's publications, aimed just at the beginner, as well as the 'Handbook' are listed on their site.

I am a beginner as well and I have to disagree with starting out with the handbook, and do highly recommend starting with Now Your Talking. The hand book is more expensive, and is complete overkill for someone who is merely exploring the possibilities. That said, if you decide to get a license, your next book is the Handbook, its the Bible of amateur radio.

And you don't necessarily need a brand new one. The essential information you need has remained unchanged since the mid 80's or so. All that has changed is the gear, and a few new communications modes have been added. Old Handbooks may have unique value for other reasons - coverage of vacuum tube gear, or historical perspectives.

Source record: 42071

I have recently become aware of the usefulness of the parts supplied by Mini-Circuits. At a recent radio rally I picked up a POS-900W VCO and TUF-5SM mixer for a tenner (about $15). I intend to use them for experimentation.

I've just finished construction of the (RSGB) simple spectrum analyser. The linearity of the VCO leaves a lot to be desired, but may be replacable with a Mini-Circuits VCO (the POS-300W, but is a bit expensive at 20 quid).

I am aware of JAB who sell some of the MAR/MAV series amplifiers and the SBL mixer. Does anyone know of any other suppliers in the UK, or even better of anyone selling off old or surplus parts. What about Birkett?

regards...

Okay.. here's an Idea.. I have a remote 5 position antenna switch on top of the tower.. how about remoting a SWR bridge up to the top of the tower (just before the switch) for a true SWR reading at the antenna.. un polluted by 150' of coax. Not good for tuning an amp, but should show the true antenna match. Any value with this? I have a HM-102 that has a remote head, but likely would have to amplify the head output before running it through 150' of wire.

Problem solved. I had mounted three of these diodes in series on a terminal strip but did not solder them because I wanted to make sure that they would do the job. One of the responders reminded me that heat is disipated away from these via the leads. There was almost no thermal contact at the connection but the electrical connections were fine. Once soldered with a tad of extra solder there is no detectable temp rise now. Thanks to all.

Alan,

thank you a lot for the response. Yes, the C3 goes to coax braid. Do you think that carefull adjustment of matching trimmers for the same values would help? I have a similar coil (not made by me) and a guy who made it discouraged us to readjust the matching capacitors. Do you think that this could be a reason why that coil tune is stable and my is not.

As far as I'm aware, the only place in the UK where you can order the
full Mini-Circuits product line is from Mini-Circuits Europe on 01252
832600. Prices may not be good, though... expect about ï¿½1 = $1.

As you've found, other dealers may have a few selected items. The RSGB
Microwave Component Service sell mostly modamps, Hands Electronics sell
some parts and so do GH Engineering. You can find all of these by a web
search.

Forget about Birkett - he's a surplus dealer so his stock is whatever he
happens to have right now. If you want what he has, then his prices are
very good; but if you want something specific, you need to go to a
regular component supplier, and expect to pay more.

Pity about the 'Simple Spectrum Analyser'. The person who designed it
more than 10 years ago is desperately trying to make RSGB stop
re-re-re-publishing it, because he knows it's out of date. The W7ZOI
design is a much better homebrew project (search for his web site).

I don't know the answer to this question. It's been a long time since I went through the calculations. The amount of local heating you'd get at the 500 watt level could be fairly large, depending on how you choose to pick off the voltage and current samples, and where the diodes are placed relative to the heat producing components.

I'd do some experimenting. If temperature is a problem, you might consider putting in a third diode with a very stable voltage across it, sensing the diode current, and using that to determine the correction you'd need.

So there is a mechanically/electrically identical coil that doesn't
suffer the same problem? That's weird. The coax feeding the other one
isn't a 'magic' length is it, say n/4 wavelength?

Are the trimmers set to largely different values (wrt each other) on the
stable coil? They may be tuning the line and breaking the shield
current (parallel resonance). Which sounds pretty unlikely to be stable
itself.

I guess you can't just wack ferrites over the coax near the coil in a NMR
application?

If you've got something that can measure RF current by induction (ie a
coil and CRO, or a diode probe) you could try tuning the matching caps
for minimal braid current a metre or so up the line from the coil.
Working on the theory that it is stray RF on the braid that is the
problem, not mechanical deformation of the coil when you move the coax
or its bulk properties changing the near field of the coil.

The lesson here is that when it comes to max. power, the manufacturer
will always take every advantage to arrive at the highest value, and
normal practice may have little resemblance to the test setup used for
the max. power spec. Either you study the data sheet closely and find
out exactly what is needed to achieve full power rating, derate
generously, or both.

I've used Slackware, SuSE 7.2, RedHat 7.2, and a smattering
of Mandrake in there somewhere. If you're running with Debian
now, you'll be fine.

My personal choice is RedHat, because I administer a bunch
of these at work, and it's easier not to shift gears. RedHat is
well-supported (meaning that .rpm's come out pretty quickly,
How-To's refer to init and file-locations that generally match
RedHat, etc).

But the folks that have chosen Debian (and Slackware!) are
usually _very_ strong supporters of those distributions. There
must be a reason...

Use whatever distro that you are comfortable with, and just add the extra
apps that you want.

Personally I use Mandrake.

Since you are currently using some sort of MS product (you uset Outlook
to post) yu might want to use one of the easier to install mainstream distros
like Mandrake, Redhat or Suse.

I'm aware of this newer design, but from my point of view there are
several drawbacks
o more expensive since it uses Mini Circuits mixers and VCO's.

(although this will give big advantages)
o only works from 0 to 70MHz.
(I want to make a 6m transmitter so I am interested in seeing
the 2nd harmonic just over 100MHz which the RSGB design can just
about do)
o the filters look more difficult to build.
o need to order the PCBs from the USA.

Is there any change someone clever person in the RSGB might design a
newer version with components easily obtainable in the UK, perhaps with
a wider frequency range?

Tonight I built the sweep generator and checked the calibration.
Seems accurate from -20dBm to -55dBm.
Over -20dBm there appears to be overload.
My signal generator only goes as low as -55dBm.

A few caps and chokes. Scrapping an old TV preamp supply would provide
all the parts. Better yet, just use a TV preamp PS and tailor the
voltage accordingly!

My junk-box contains 40 years of things bought from surplus dealers because they looked useful - but they hardly ever are. Occasionally you get lucky, and drop on just the weird part you wanted... but it's usually about ten years too late.

>> The W7ZOI
>> design is a much better homebrew project (search for his web site).

>about do)

Or more likely, not quite do in the standard configuration - every MHz above 90MHz is a struggle. However, since the VCO in the G4PMK design is built from discrete parts, for a special job you can always tweak the whole coverage upwards, say from 20-110MHz.

> o the filters look more difficult to build.
> o need to order the PCBs from the USA.
>
Ordering the PCBs from the USA is no big deal, these days.

The same applies to ordering Mini-Circuits parts, except that M-C USA probably won't accept orders from a UK address - they'll insist that you order from M-C UK. The answer is to find a friend who will order them from a US address, and then send them to you as a private 'small packet'. M-C may not like it, but it is totally legal.

The bonus is that for a reasonably small declared value (maybe up to about ï¿½60/$100), UK Customs are much more likely to waive charging VAT and import duty on a private parcel than one from a commercial company - even when the green Customs label is the same. Occasionally you will get

hit, and then it feels horrible... but it's still probably less than
you'd have paid M-C UK.

Returning to technical issues... apart from the more limited frequency
coverage, the W7ZOI analyser design has one overwhelming advantage over
the G4PMK design - it works better!

Of the G4PMK design, you say:
> Over -20dBm there appears to be overload.
That is a serious problem when you're trying to measure harmonic levels.
The better the harmonic suppression in the TX, the more likely it is
that the measured harmonics will be generated in the front-end of the
analyser.

>Is there any change someone clever person in the RSGB might design a
>newer version with components easily obtainable in the UK, perhaps with
>a wider frequency range?
>
Sure - his name's Gary Morton!

Unlike the ARRL, the RSGB isn't big enough to have its own lab or
technical staff - but even in QST you'll notice that the vast majority
of designs and projects come from individual amateurs... like W7ZOI.
With RSGB it's even more so.

Quite seriously, I think that if you set about designing a "born in the
UK" HB spectrum analyser, you'd end up very close to duplicating what
W7ZOI has done. The better a designer you become, the more likely you
are to arrive at the same conclusions as W7ZOI about the optimum system
architecture. Likewise, you'd probably end up using Mini-Circuits,
because nobody else on the planet makes a comparable range of reasonably
low-cost components.

Technically they aren't the very best, but in most cases they're better
than anything you could build without extensive test equipment. You can
drop them in and know that at least those parts of your circuit perform
as specified.

Equally important, they are *available* - easily in the USA, and in the
UK they are probably still the least difficult option.

Hello

I Need my old 2 meter mobile rig the subtone units, only schematics diagram
is OK. Rig is Kenwood TM-201A Europe model. and unit is TU-3.

Please send someone for schematic for me by EMail.

oh2bne@hotmail.com

kari.palvo@luukku.com

I have for sale 1 full size "HY-Gain" beam 10 meters. fully assembled for your inspection. 13' Boom and longest element is 22' $100.00 I also have a steel tower totaling 25'. this is in 3 sections 1 10 foot st8 and 1 5foot st8 and 1 10 foot top section. I don't not have a rotator. $50.00. pickup only from Nashua,NewHampshire. I am selling these because they are to big for my new QTH. This beam has spent a large portion of its life in storage. 73's Jeff AA1GR

If you don't mind buying vs. building, this wonderful little
widget...

http://www.advancedreceiver.com/page26.html

...will do the job nicely. I'm using one here to feed DC to a high-
end active GPS receiving antenna in my mobile. It works exceptionally
well, no performance problems at all, and it's good to at least 1.5GHz.

Keep the peace(es).

Hi there!

we build up a new website wich is NON COMMERCIAL and without any ads.
The site contains information about Magnetic Loop Antennas for shortwave.
We would be happy if we can find some postings and exchange of experience
inside the webboard. We would be happy if you take a look and leave some
interesting question or infos on the board.

http://www.magnetic-loop.de

Thanks a lot!

How much are you prepared to spend and what do you need? Do you really want to build it? IF so, great. Otherwise get a surplus HP for a few £100 or use a commercial scanner.

For example, the ICOM PCR1000 wideband receiver can be used as a basic spectrum analyser with the right software (from the web). You need to add a front end switched attenuator, especially if you want to make amplitude measurements and you will need to calibrate the amplitude response, but otherwise that is it for a 100kHz-1.3 GHz synthesised analyser.

>For the record, we also have 8 pints to a gallon. But our pints
>are 16 unces instead of 20. Our ounces are the same size as
>yours,

Oh that it were that simple....
The US gallon is defined as 231 cubic inches, which means that
a US fluid ounce is 29.5735 cubic centimeters
The imperial gallon is defined as the volume occupied by 10 lbs
(weight) of water at 62 deg, which means that an imperial fluid
ounce is 28.4131 cubic centimeters

>so the net result is that our pints, quarts, and gallons are 4/5
>the size of the imperial versions.

From the above, the US pints, quarts and gallons are very close to
5/6 of the imperial measures.
To be more exact, the imperial gallon = 1.20095 US gallons

> Here, a "pint's a pound, the world around" (pint of water, that is).

I do not follow this. The US pint is a measure of volume.
Presumably this works at some specific temperature.

>There (imperial), a "pint of water weighs a pound and a quarter".

yes, but only at 62 degF, as per the definition.

> I'd like to feed +12VDC from the shack through the coax to a mast mounted
> preamp operating in the 223 MHz range. Does anyone have pointers regarding
> accomplishing this project?

F. d T. posted the basics: just feed the DC in one end through an
appropriate choke, and get the RF back through an appropriate
capacitor, and do about the same thing at the other end to feed RF
(through a cap) and receive the DC (through a choke). At 200MHz, you
should do fine with something like 220pF to 1000pF caps, and chokes in
the 220nH to 1uH range. (Beware of chokes with self-resonant
frequencies lower than your operating frequency.)

You can just feed a voltage in, and that may be fine, but there are a
couple potential problems: first, if you happen to disconnect the
coax and for some reason it gets shorted (e.g., center conductor
touches ground), you can draw quite a bit of current. Some protection
is nice. Second, depending on the current you're drawing in normal
operation and the length of the run and the condition of the
connectors, you may have more voltage drop than you really want. One
way to get around both these potential problems is to feed in a
current source instead of a voltage source (still using the chokes and
caps to separate the DC and RF), and have a shunt regulator at the
preamp end (perhaps just a zener diode). If the current source
doesn't mind being shorted to ground, that solves the first problem,
and if the current source can't put out enough voltage to actually
damage the preamp even if the regulator at the preamp end were to
open, then things are fairly well protected (though not against
external things like lightening, of course!) Another thing you can do
using this method is to feed a variable current, which results in a
variable current in the shunt regulator, which can be used to set a
tuning voltage or control a relay. I've done this for a VLF preamp,
and it worked very well...excellent stability, and you only need the
coax between the preamp and the power supply/tuning control/receiver.
The complexity is obviously greater than just two caps and two chokes,
but the results were definitely worth the effort in that case.

Cheers,
Tom

You have a filter here if I'm understanding your diagram. At these freq's
it is very easy to detune a filter by messing with the grounds in any
way. The technical term is non monotonic behaviour, but it means that the
filter is not very theoretical in response. The only thing I could advise
by remote observation, is to make sure that you have lots of ground

everywhere and then double it. A shield between in and out would also help (maybe). Remember, RF is a big pain and it is directly proportional to the frequency.

It helps with pictures such as this to take it outside and place it in the shade. Outside provides the high light level that digital cameras like to have, and the shade provides diffuse light that minimizes "shiny spots" from the components.

Up close is bad since the center components will be in focus and the outer components will not. I have found it is better to back off about 2 feet and zoom into the circuit so that focus is uniform across the picture.

That said, the layout looks a lot like a 4040 rig as someone has already mentioned. This is a pretty standard set up. Ne602 front end, crystal filter IF, NE602 IF detector, LM386 AF amp. A second NE602 is used for TX mixing, so there are three total. In this rig, the volume control was connected to the RF input and attenuated the RF in order to set the audio level output.

There appears to be no MC1350 IF amp, so it is not something like a Norcal Serria.

PSK31 is transmitted using audio tones modulating a SSB transmitter.

Hi Mike,

I've been checking out Ebay for spectrum analysers and they go for
several hundred pounds. From second hand equipment suppliers they don't
appear to be had for under 1000 quid. My interest is really in the
building and learning as I'm new to RF.

regards...

Not necessarily. Because he only needs to cover a few KHz of
the 20M band, he could generate the carrier at signal
frequency and remove the opposite sideband with a simple
crystal ladder filter. The good news is that it is
very simple, the bad news is that he will have to buy
several 14.070MHz crystals.

This is quite easy to do on 80M because the PSK31
calling frequency is very close to 3.579MHz. You
can use cheap colour (or should that be color for
NTSC) TV crystals.

Guys,

I really appreciate all of your responses! Shows there's still some technical expertise within
our ranks. I pawed through my ARRL stuff and didn't see this technique addressed, even
tho it's been standard TV practice for many years.

Since the preamp is using F fittings, I ended up following your suggestions by scrapping an
old 2-port TV splitter. Fed a 12 VDC Wall Wart to one of the F fittings and used the existing
inductance on that port to block the 223 MHz RF. Also used an existing 6 pF cap for
coupling and DC blocking. These values may not be optimum but I only measure a barely
perceptible difference in signal output, using either direct DC feed or the voltage inserter.

Thanks again guys, you got me up and running!

I think Small Wonders Labs has a 20m 5w QRP PSK31 rig.

http://www.smallwonderlabs.com/

Look at the PSK page.

What so special about PSK31 ?

Various forms of PSK are usually generated by I/Q modulators,
essentially a phasing transmitter.

Shouldn't it be possible to have

* a RF signal source (in this case a crystal oscillator or VXO),
* an RF phase shifting network to generate the quadrature carrier
(simple in this case due to the fixed frequency),
* two modulators (NE602, SBL-1 etc.),
* baseband filters for premodulaton shaping
* a linear power amplifier (due to premodulation shaping)
* a digital signal source (PIC, PDA, PC etc.)

to generate various sorts of PSK signals, not just PSK31 ?

Zener diodes are sometimes used for generating wideband noise (audio to 30 MHz), see e.g. http://home.earthlink.net/~n0ss/noise_source.pdf using a 6.8 Volt, 1 Watt zener diode.

The noise is probably seomething the manufactureres try to avoid from a zener diode, but what determines the maximum noise? Is there an optimum zener voltage, power dissipation spec, or an optimal operating current, ...?

If I remember right there is a voltage where the temperature dependence of the voltage is almost 0 (is it 6.2 Volts?) Is there any correlation between noise and temperature coefficient?

I don't have hard rules, but I think I remember that higher voltage
zeners are noisier, and running them at very low currents also
increases the noise output. They are pretty high impedance sources at
low currents, so you should buffer them if you want to maximize the
energy at high frequencies.

I know that if you get it right, then it can be a very nice and clean system. I have seen several versions where the Tayloe method has been decried, but usually due to poor construction and lack of attention to details (and ballance).

Like the pix, looking forward to the circuit. Where did you get the dial?

Thanks, gentlemen, for the correction. I had spent my life until now believing that the Imperial gallon was equal in size to five of our quarts. And somewhere along the line I got a wrong definition of an Imperial ounce, solidifying the misinformation. As you point out, it's more like 1-1/5 of our gallons (very close in fact).

By way of an excuse, the only time I encountered Imperial liquid measure is on a few trips through Canada long ago before they metricized.

I'm glad you spoke up. It hopefully prevented the misinformation I posted from circulating farther, and I certainly learned from it.

Let's just all go metric and forget about it. In my last trip to the U.K. a couple of years ago, it looked like the liquid measure (at least petrol) has gone metric, although the roads and vehicles were still marked in miles (inexplicably abbreviated 'm') and miles/hour. Keep at it.

Yeah, but a very simple fixed tuned SSB transceiver like the
PSK20 ($95 kit, $140 with custom cabinet, size of a modem,
requires 2A at 12V from a wall wart or battery, makes 5 W PEP)
works with a PC with sound card.

With software like Digipan you can "tune" anywhere in the
audio passband (think of it as a tunable IF with digital filtering
and software demodulation), which covers the entire area of
interest between14.070 and 14.073. The PSK is generated
and decoded in software on the sound card equipped PC.

With software like WinPSK, you can even monitor several
different transmissions at the same time, and reply to any
one of them with just the click of the mouse on the waterfall
spectrum display. Very convenient.

If you want a different PSK modulation (or even a non-PSK
modulation), there is software available to do that too using
this same hardware system. All you do is load a different
program. Write your own if you like.

I carry my PSK20 in my laptop bag when I travel. I can be
setup to operate a couple minutes after I rig an antenna.

(I usually use a simple wire dipole and a tiny MFJ tuner.)

This is pretty much a software defined radio. Many of the functions normally done in hardware are done in software at "IF" by the sound card equipped PC.

I think you will find it is a function of the voltage, temperature and junction surface area. Zener diodes (and LEDs) have a pretty big SA so they are good at generating a lot of noise. They also make good varicap diodes, although LEDs are not too much use as varicaps at VHF.

Try a Zener of decent power diode and warm it up with a few added volts. Use a 33v diode and give it 24 volts of "grunt". Makes a lovely generator of noise.

B.R. from Anony Mouse (Harry Lippitz, really, but I don't want to publish my name.)

Ordinary junction transistors also make good noise sources. The base/emitter junction when reverse biased acts like a zener at approximately 7 volts for most common silicon transistors. It has the same noisy characteristic. There is considerable variation from device to device, so make a quick test setup and run through a handful of 2N3393's or something similar and pick out your favorite.

Don't run these noise tests too long or you may begin to hear voices buried in the noise. :-)

There is an optimum current, typically a few milliamps or tens of
milliamps for small devices, where the noise output peaks. Right on this
peak is the most stable and repeatable place to operate the noise
source. At lower currents the noise reduces, and then starts to rise
again at very low currents. You can get lots more noise in the
low-current region, but there it is extremely dependent on the current.

>If I remember right there is a voltage where the temperature dependence of
>the voltage is almost 0 (is it 6.2 Volts?) Is there any correlation between

Sorry, I don't know about any parameters other than current; and my
experience is only with HF upwards - I can't be sure about audio and VLF
noise.

: must be a reason...

Security, mainly. If you're running Linux in your home computer with casual internet connection via modem, and running no services, RedHat might be OK. For servers with direct connection to internet I wouldn't recommend it.

RedHat used to include in their distributions outdated versions of network software with security holes. I used to run Slackware, not that easy to install, but no one ever broke into my machine (and they tried hard!). Installed RedHat into a new server, and it was hacked two days later, a quick search showed security holes in pop3, imap and the ftp daemon (the later was a version with a well-known security holes). Most of the included software (gcc, gdb, X apps...) were also outdated versions compared to the Slackware distribution ones.

Now I'm running SuSE (6.0), and it is pretty secure (no problems so far). I gave a try to RedHat again a year ago (version 7.0), and had again a negative experience: the machine was hacked again during christmas and the hacker did considerable damage (I should have expected it). I guess I won't be trying any RedHat again.

Hector.

I believe I've mention this before but in case it was missed.

We have a short "interstate" highway, I-19, that runs from Tucson to the Mexican border at Nogales, AZ.

In order to aid the Mexican illegal drug haulers and to make the illegal "immigrants" feel right at "home", the federal government has decreed that the road signs will be metric. Distances are posted in meters and kilometers, so we have "mileposts" that are really "kiloposts" and signs that tell us that it is 500 meters to the next exit.

But in a fit of bureaucratic schizophrenia, since this highway is still in Arizona and Arizona law sets speed limits in miles per hour, the speed limit signs are in mph. Is this a great country or what?

And as a further example of greatness, you U.S. taxpayers should be pleased to know that a massive multi-year expansion of this highway has just begun in order to speed the flow of unsafe Mexican trucks and drivers into the country. Safety checks of these trucks by local authorities will not be allowed because this might interfere with our "free trade" agreements with Mexico.

Wes

ps. One further attempt to metricize is that when an occasional load of illegal drugs is seized, the authorities give the weight in "kilos." It's a start.

Of course. I plan to put such a system together this
winter - baseband I/Q out a PC sound card, then an
RF modulator and power amplifier. With such a setup
you can generate just about every form of modulation
hams use today.

This is incompatible with ricebox technology, so I
doubt anybody else will be interested in it.

I hope you have a sound card that has a frequency response down to DC.
At least some CODECs have some kind of offset compensation (similar to
auto-zero in DVMs) at the analog input, thus, the analog input behaves
as if it contained a high pass filter around 3 Hz.

>This is incompatible with ricebox technology, so I
>doubt anybody else will be interested in it.

I have often wondered, why baseband I/Q (zero-IF) modulation and
demodulation has not been used more frequently in amateur digital
systems. Just look at the large number of I/Q chips available from
e.g. Maxim.

I should point out that breaking down the emitter-base junction can
cause a reduction in transistor beta, although it's a cumulative thing.
Don't know if a short test like that would degrade most transistors, but
you should consider it before going through your whole box of transistors.

1790. Direct conversion spectrum analyser

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-24 01:30:47 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3d66e02b$0$20680@echo-01.iinet.net.au>
Source record: 41952

Dear all
I am toying with the idea of a spectrum analyser based on our LO design for
1-2 GHz (yes it is still coming! - see http://www.qsl.net/ke5fx/index.html
for details)

The software/display would be PC based
Linux C++ for software
Sound card for filters/log det/monitor receiver

Front end would LO to diode mixer
First IF at 1000 MHz with roofing filter
Sweep would then be from 0 to 900 MHz or so

1000 MHz LO to mix down to audio (direct conversion)
It might be possible to use an I/Q setup with two mixers though I will need
a different audio setup for 2 inputs
?DSP board
Alternatively a conventional multiconversion to (say)
80-100 MHz/10.7 MHz/455 KHz though this would be rather more complicated.

I appreciate there will be "hole" at 0 Hz in the audio response with a DSB
direct conversion setup.
I presume this could be got around by dithering/stepping the LO frequency
and summing the resultant outputs
(the LO can be digitally set to better than 1 Hz resolution)
The PC itself may be the source of RF noise but I presume this can be calmed
with shielding techniques.
A limiting factor for fine resolution/sensitivity will be the LO phase noise
which is not as good as a commercial analyser but I would think it would be
possible to have useful measurements to a resolution of 500 Hz or so which
would be good enough for IMD tests etc.

Has anyone seen/had experience with such a setup and if so, are there any
fundamental problems?
I have seen the PC based amateur transceivers which cover a very wide range
and seem to function pretty well.

Thanks
Richard

Source record: 41957
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

I have several old Army surplus custom made tube- type training power supplies. These contain several useful parts (including the case) for making a 50 or 100 W RF amp or transmitter out of. Total size is 19" W x 15" D (counting the 3" handles on the front) and 8" H. The front has two nice large 4" x 4-1/2" rectangular Simpson panel meters, a 500 V and a 300 mA. Also has a 3-pos rotary sw and 3 pots, all with nice black knobs, and a fuse holder & rocker power switch. Inside is a big plate/filament transformer with the following spec: Stancor P-8352 with the following ratings: Pri 117 VAC, SEC: 290-0-290 (580 VCT) @ 240 mA DC, 5 V @ 3 A and 12.6 VCT @ 5.25 A. There are 4 tubes in the unit: 5V3 Full Wave rect, 6AS7G large octal power reg, 6136 mini 7-pin and a 5651 87V gas VR tube. Also has a 20 uF / 500 V dual section twist lock capacitor, and some power resistors and other parts. There is no top or bottom cover, but I can supply a piece of 1/16" aluminum to fit. I traced one of the units out before and drew some rough schematics, but never got around to drawing a good on out. Asking $30 plus UPS (36330 zip, total wt appr 28 lbs). Also have units missing tubes or other parts (several have broken meters) which I will knock $5 or $10 off. I can email you two photos. Email or call 334-347-5281 day/eve.

Good luck. I tried changing my I/Q system to use
a sound card and PC to replace the DSP evaluation
module. I never could get phase synchronization
between the I and Q samples. (The sound card
operates sequentially for left and right, and you
can't precisely control the timing.)

That's why I gave up on that approach and simply
do the modulation of the carrier while still in the digital
domain. Then one channel of the sound card is used
simply as a D/A to output the modulated signal at an
audio IF. That goes to a conventional SSB transmitter
for up conversion. That gets rid of all the uncontrollable
timing problems.

There have been a number of articles in the QRP Homebrewer and QQ, if I recall, on simple PSK rigs. You might check the NJQRP site, http://www.njqrp.org, most probably there are schematics of an 80 meter PSK rig that could give you ideas.

Also, you might check the DL-QRP club at http://www.werdau.net/dl-qrp-ag/. The transmitter circuit from their Black Forest rig might be pressed into service. I'm not a German speaker but it appears there is more on their German language pages than their English pages so there may be something else there useful, as well.

You might also try emailing Peter, DL2FI, who is the engine behind DL-QRP. He is one heck of a fun guy and a bundle of ideas. (Also a recent inductee to the QRP Hall of Fame).

Hallo!

One of my friends owns an old "Atlas 210x". Now he wants to use it as his "digital modes Transceiver" because the receivers spectrum is very linear. But it has a terrible frequency drift problem.
Now he remembered that there is a connector for an external VFO at his radio's rear. His idea is that there must be a way to stabilize the radio on the frequency - for example 14.070 for PSK31. May be with a little circuit using crystals, etc...

Do you have any ideas about how to do this? Schematics? Or something that may help him...

Thank you very much!

5 watts is way to hot to grid drive a pair of 6146s. But you can always swamp it down a bit with some resistance. Or even make it link coupled and make it a loose coupling.

You can probably get away without changing the tank circuit. Use the 20 meter band and see how that works out. If not, then try the 15 tap.

Just some thoughts.

1802. Using old TX as linear?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-25 19:58:38 UTC
From: n2cqr@clix.pt
Message-ID: <3d6936c5.597395154@news.clix.pt>
Source record: 41964

I recently built a solid state 17 meter SSB transmitter and have been having a lot of fun with it. (Details on my web site -- URL below). The only problem is that the 5 watt output sometimes makes copy tough for my 17 meter friends. They are threatening to take up a collection to buy me a linear.

I tried using a little Ramsey kit 20 watt MOSFET-based linear. Those MOSFETS are too sensitive!

So... I've come to my senses and am looking at alternatives that glow in the dark.
After building the transmitter, I don't want to immediately launch into another HB project. This morning I was sitting in the shack. I was looking at the old HT-37 that has been JUST SITTING THERE for a long time. Two nice 6146s in there, already wired for linear service. Power supply already built. You guys see where I'm going.

How about me running the 5 watts of RF out of the HB 17 meter SSB rig into the PA section of the old HT-37?

Any suggestions on how to do this? I'm looking for ideas that don't involve major surgery on my beloved Hallicrafters TX.

Should I run the RF stright to the 6146s? Or should I make use of the 12BY7A driver? How much drive will I need for the 6146s?

Do you guys think I will have to change the values of the coils in the PA tank and/or the driver plate circuit? Or will I be able to tune 17 with the bandswitch in the 20 or 15 meter positions.

Suggestions welcomed. Thanks,

Hello All
I have aprox 40 lbs shipping weight of all sorts of really good parts.
Might be a little less or maybe more i have a bunch of hard to find
items and will fill the box up.
17 Ceramic bandswitches every one will handle legal limit + .
Some really Nice Air Varaibles big and small ones.
3 varaics
Tubes 3-813's, 1- 811, a bunch more tubes all transmitting tubes
5 panel mount meters
A nice collection of knobs
Aprox 12 lbs of ceramic and regular tube sockets
Plate choke with plate resistors and caps for 2-811
handfull of ceramic plate caps big and small
really to much to list individually. I have some pics if your interested.
There is alot here.
would like to sell it all in one shot, Make me an offer i can't refuse.
Chris NI4L

Question:
Presumably just with hot water?
Detergent could/would corrode components?
Reason I ask is that telephones 'put through a dishwasher' do
not, generally, work very well afterwards!
Curious. Terry.

Source record: 41972

You will need to link couple it if driving the 6146 grids. They are biased with about 50 volts of
bias. You need to reach that to drive them. 5 watts at 50 ohms is only about 15 volts. You
could put a small 2 turn loop around the driver coil in the ht37's grid coil. You will then need to
provide a load on the 5 watt transmitter. A 50 ohm resistor would probably do it. Just run a
small piece of coax out of the ht37 from the little link.

If you drive the 12by7 grid you can probably just couple in with a small capacitor to it. You still
need a 50 ohm load on the solid state transmitter though. I would go for the link at the 6146
grids. Probably best to pull the 12by7. Should work great.

One continuous rigid piece 17 feet long would be hard to ship, except
by motor freight, and hard to transport. I also assume this is not for
mobile use unless you bend it way over.

You would either need a more flexible one that could be coiled.

A more practical arrangement might be to have a 100" whip and a
loading coil.

Do you need it to stand straight up or are you going to bend it over somehow? If its the latter, the messenger wire (.109 and .134") from CATV self-support distribution cable could work ok.

Take a look at the famous fiberglass telescope mast made in Germany:
http://www.qsl.net/dk9sq/fibregle.htm
Sold in U.S. by http://www.bright.net/~kanga/kanga/dk9sq.htm
Use as many sections as you need to obtain your desired length (up to 33ft).
Put a simple wire inside and you have your whip.
Am using it for many years as fixed HF antenna, combined with an SG-230 auto
tuner.

Well I joined the group, but not very impressed so far
the problem is going to be finding interesting projects,
talking about old back copies of the Radioconstuctor
is a bit boring, the trouble is these days very few people
build anything, usually just grey heads (like me)
Most of the work I seem to do these days is modifying
existing stuff, like making a Packet tnc from an old
Rabbitt fone base, and interfacing a computer with an
old PMR radio, and that sort of thing, but its very personal
others would probably find that boring as well hi!

Use a detergent designed for electronics. Anything containing
phosphorous or chlorine compounds should be avoided.

You try my freq counter/stabilizer at
http://members.iinet.net.au/~richardh/vfostab.htm

This will stabilize the VFO if it drifts less than about 5 KHz and provide a
freq readout.

> for details)
> (snip...)

I once hacked together a VHF direct conversion spectrum analyzer to help align the LO chain in a receiver, and it worked fine. It was as simple as I could get away with, an op amp ramp generator, a Mini-Circuits VCO, a mixer, and an audio amplifier. The ticketaticketaticketa sound was clear from the audio output, and hooking the mess up to an oscilloscope showed a crude but useful display. It told me what I needed to know, and I aligned the LO on the correct harmonic.

I never zoomed in closely enough to see the image response, but I knew it was there. Since you know exactly what's wrong with the output, it would be a simple matter to deconvolve it in the computer before displaying it.

re: Convertacom HT to mobile vehicle adapter (Motorola)

Hello there,

I'm pulling my MT-1000, HT-600 & P-200 Portable Covertacom out of service today. It's the drop in power supply, battery charger (dual rate... fast and slow), external amplified speaker (high power version) included and the mounting brackets.

I bought and have been using this unit for some time now for both UHF & VHF Motorola Portables... works very well with all the above models. We are going to trunking...

Paid almost $400 for it some years back... I'm asking $65 or best offer now. Drop me a direct Email if your interested... Please no spam or junk Email...

I'll also be listing a number of used HT-600, P-200 and one or two MT-1000 radios here in the next week. Watch for my listing... check my all positive Ebay feedback (my Ebay ID is my Email address you see here) for references.

thanks

1825. ARRL Maryland-DC Section Convention & Hamfest

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-27 00:03:10 UTC
From: "E. Allen Brown, FALLFEST 2002 Programs Manager" <KZ3AB@ARRL.net>
Message-ID: <3D6AC1BE.DB706AE4@ARRL.net>
Source record: 41988
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatachors,rec.radio.amateur.homebrew

The Foundation for Amateur Radio (F.A.R.) and The Columbia Amateur
Radio Association (CARA) have joined forces to create what will
become one of the premier Amateur Radio events in the Mid-Atlantic
region.

The dates are Saturday, September 7 and Sunday, September 8, 2002
at the Howard County (MD) Fairgrounds west of Baltimore near the
intersection of I-70 and MD-32.

See: http://www.fall-fest.com/ for details and directions.

VE Exams (amateur radio tests) will run from 8:00 am - 12:00 n
on Sunday, September 8.

Skywarn classes run from 12:00 N - 5:00 pm on Saturday,
September 7. See: http://www.fall-fest.com/skywarn.shtml
for info on how to register.

Many vendors have reserved space including "Satellite Sam," the
"RF Connection," the "Badge Man," "Startek," "Ramsey Electronics,"
and more.

Seminars will include:

Amateur Microwave Communications with Bill Seabreeze, W3IY
RF Interference Investigation with Mike Martin, K3RFI
AMSAT Satellite Communications with Rick Hambly, W2GPS
Coordinated ARRL Presentation with Tom Abernethy, W3TOM, ARRL MDC SM
Demonstration of the Marconi Detector by Chip Weems, W4PBG
APRS Demonstration by Bob Bruninga, WB4APR
Amateur TV demonstration by Tim Keener, N3VGS

And more!

A special event station will be on the air demonstrating vintage and
homebrew equipment (radios that glow in the dark) with that wonderful
rich
sound of AM radio from the "old days."

For more info, contact: <info@fall-fest.com>

A longe whip is only 6 feet with a 1 foot popper.

IMHO you are better off using restraints and a riding crop. It
adds that personal touch.

Came in different diameters, all in three-foot increments which could be
screwed together (thicker toward the bottom, thinner toward the top).
For field day I once erected a 33-foot version (BY MYSELF; it was like
trying to stand up a 33-foot piece of limp spaghetti!), but it had to be
guyed at least twice, IIRC. I don't remember if a 16-17 foot version
was self supporting, but that'd be close to the limit.

I also purchased the base insulator and mounted it in the center of
my vehicle's spare tire.

I have used a few of these dials in my projects. They have a 6:1 or 36:1
reduction drive built in. You get 36:1 over a certain range of motion then
the 6:1 kicks in. Stop turning and turn back the other way and you're in
36:1 again. It's quite intuitive and nice. With my Huff Puff VFO Stabiliser
I have lock points separated 11.9 Hz in my 80m receuver with my current
circuit settings, and I can quite easily move the VFO up or down just one
lock point in the 36:1 mode.

I inherited them from my late Father, and had no idea where they could be
sourced until a few months ago, when I received an email query and asked on
this newsgroup and a couple of other places. I found the dials were made by
Jackson Brothers here in the UK, who are now owned by Mainline Electronics
Group. I got a catalogue from them and offered to build them an online
version for their website (in fact, they had no website only the domain and
a message about it being down for maintenance).

See http://www.mainlinegroup.co.uk/jacksonbrothers/index.htm for the result.

1829. Professional circuit boards

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-27 13:46:58 UTC
From: smorrisby@cix.compulink.co.uk
Message-ID: <akfvsiicu1@thorium.cix.co.uk>
Source record: 41992

How do manufacturers finish off their circuit boards with that green (I assume) silk screen printing. I can make and populate what I believe is a good looking PCB, I can even print on the component locations, but they never look anything like a professional one. How do the pros do it and why do they use green anyway?.

Thanks

Steve

1830. How CONNECT to a Ufer ground?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-27 14:41:16 UTC
From: mcalhoun@ksu.edu
Message-ID: <akg32c$hrv@unix2.cc.ksu.edu>
Source record: 41993

Several weeks ago I posted a question about how to provide a really-good ground in the new basement that'll soon be built beneath our house, and several respondees suggested using a "Ufer" ground. However, after studying them, I now have more questions:

HOW does one make connections to the rebar INside the footing?
Does the contractor just leave some rebar sticking out here and there?

If s/he leaves a few inches sticking out on the INside of the footing, that will be BENEATH (or in) the slab floor, so I won't be able to connect to it. Maybe "out and up" or "up and then out"?

(FWIW, my contractor says there will be no rebar in the slab itself, just some kind of fiber mixed in with the concrete.)

If a few inches of rebar are left sticking out OUTside the footing, what keeps that rebar from corroding from contact with moist soil and thereby quickly becoming useless as an electrical connection?

Incidentally, I spoke with a representative from the local power company yesterday, and we concluded that the new electrical service entrance should enter at a spot that (probably unbeknownst to him, since all he considered was code regulations for closest distance to windows, decks, and overhangs, maximum runs, etc.) is almost optimum for a "common entrance" for electricity, telephone, and my antenna coaxes!

A minimum Ufer consists of 20 continuous lineal feet of half inch
rebar jacketed in a minimum of 2 inches of concrete. Anything much
smaller won't be markedly better than an ordinary driven rod. So
messing with short bars in the footing probably won't accomplish
much.

Where the Ufer technique really shines is when you have a bonded
grid of rebar in a large slab. Then the contact area gives you a very
low impedance connection to Earth.

If it were me, I'd slip the contractor a few extra bucks to lay in a
bonded rebar lattice for the slab. That'd get you a great ground.
Have one end of one of the rebars bent up above the slab surface
so you can tie to it.

>If a few inches of rebar are left sticking out OUTside the footing, what
>keeps that rebar from corroding from contact with moist soil and thereby
>quickly becoming useless as an electrical connection?

Nothing. That's why a real Ufer ground requires the rebar to be
fully jacketed in concrete.

Can you just weld the rebar sections togetherwith a conventional
welder to get the "bonded" connection you refer to?

Sure, though that's probably overkill. You can just wire tie them
together at the crossovers.

He apparantly lives in an area where it is cheaper to use fiber reinforcing (expensive material) instead of wire mesh or rebar (expensive labor). Before the advent of fiber, there used to be experiments with metal needles, which would do roughly the same job and did give your slab a small metal content.

Here where labor is cheap (plenty of subs use day labor to dig their trenches and wire up rebar) most contractors will build with a rebar ring round the edge of the foundation and wire mesh spread across the center. Six gauge wire mesh will give a great ground, it is 5 foot by 150 foot rolls of 6in mesh, with welded crosspieces. Never have I seen rebar welded together in residential construction.

Another alternative to rebar is the tension wire bundle used in commercial construction, it is stretched across the foundation and the ends have to extend past the concrete so that they can be tensioned. Even exposed to some weather, I have seen ends still sticking out 10-15 years later.
thanks, John.
KC5DWD

If you can get it past your local building inspector, more power to you. The problem is, that they are more worried about a slab cracking apart and shifting, than they are in getting a good rf ground

The Ufer should be the rebar in the slab and the footings all connected together. CAD welding is the preferred method, but some claim that a double wire-tie, extra tight, will suffice. The connection point to that grid of rebar should either protrude inside the structure (perhaps inside a wall) or outside the structure (into the air). That connection point needs to be near the electrical service entrance, which hopefully will be near where your other lines enter the building.

If inside the wall you will need to provide access (eg a blank cover plate) to the clamp connecting the ground wire to the rebar.

> (FWIW, my contractor says there will be no rebar in the slab
> itself, just some kind of fiber mixed in with the concrete.)

Typical, that is much less labor intensive (but some of the savings is consumed by the more expensive concrete). How much extra would it cost for rebar in the slab? You really want that if you want a good ground...

Make another silkscreen with the traces and component numbering only, no pads, and screen the board after etching it. Had to do at a company I worked for a number of years ago. Takes a long while to get it right.

Right - this is the dividing point between the Zener and Avalanche
breakdown mechanisms.

When I worked at Fairchild Semiconductor Diode (more years ago than
I care to remember) we tested 6 volt reference diodes by dunking them
in silicon oil baths at -55 and 100 degrees C while storing their
expanded breakdown knees on a Tek 564 storage 'scope. Where the knee
curves crossed, the current was noted and this was the true current and
voltage where zero TC occurred.

IIRC, the noise is contributed by a microsparks mechanism - these can
actually be seen under a microscope viewing the unpackaged chip in
darkened conditions, manifesting itself as a blue glow under the
passivating rings. Blue LEDs in 1965! I did note that 10-20 volt
"zeners" lit up brighter than most, particularly when driven with
lots of current...but that may have been a pecularity of manufacture.

The old DIP-style MC12xxx chips are getting rather hard to find. Try eBay, or one of the obsolete parts-vendors at www.findchips.com.

The MC12080D is one of the few parts from that series they're still making (http://www.onsemi.com/pub/Collateral/MC12080-D.PDF). It's a darned nice part, too -- selectable division by 80, 40, 20, or 10 well past 1 GHz. But it's only available in an 8-pin SOIC, with half the pin spacing of a DIP. A little tougher to solder to but not impossible.

Hi,
about a year ago (in the summer of 2001) there was an article in QST
with a x-tal controlled transceiver specialy intented for PSK31.
May be this information can help you because may be someone can
provide you a copy.

Good luck,
Chris PA3CRX

1848. Re: Zener diode as noise generator

Most interesting.

I looked briefly at using a zener as a noise source, and checked a number of them on a Tek curve tracer long ago. What I saw with zeners of 12- 15 volts or more was a region at pretty low current (around 50 - 100 uA as I recall) where the vertical line was very visably fuzzy, indicating movement between two voltage points. Sure enough, when I biased one of these at that current level, there was a whole lot of noise. At the time I was interested in an HF noise generator, so I didn't see what the noise did at higher frequencies.

I recall noting that there seemed to be two distinct levels the diode was switching between. That's consistent with your spark explanation.

|>
|> Jerry W4UK
|
|He apparantly lives in an area where it is cheaper to use fiber reinforcing
|(expensive material) instead of wire mesh or rebar (expensive labor). Before
|the advent of fiber, there used to be experiments with metal needles, which
|would do roughly the same job and did give your slab a small metal content.

Here in Pima County, AZ, contractors do not typically use rebar in slabs.
Footings are required to be reinforced by code. I added a garage to my house
and specified rebar in the slab as my concrete contractor (also a ham) said the
the wire mesh was a waste.
|
|Here where labor is cheap (plenty of subs use day labor to dig their
|trenches and wire up rebar) most contractors will build with a rebar ring
|round the edge of the foundation and wire mesh spread across the center. Six
|gauge wire mesh will give a great ground, it is 5 foot by 150 foot rolls of
|6in mesh, with welded crosspieces. Never have I seen rebar welded together
|in residential construction.

Welding some rebar is problematic. I believe it has to do with the carbon
content and possible embrittlement.
|
|Another alternative to rebar is the tension wire bundle used in commercial
|construction, it is stretched across the foundation and the ends have to
|extend past the concrete so that they can be tensioned. Even exposed to some
|weather, I have seen ends still sticking out 10-15 years later.
|thanks, John.

Post-tensioned slabs are used in areas of expansive soils. The concrete is
placed without reinforcing bar or wire. Steel cables are placed in the slab and
after some cure are tensioned with hydraulic rams and the ends of the cables are
terminated while under tension.

The cured slab is then essentially free to "float" on the earth with the cables
keeping it from cracking. However, the cables would make lousy ground as they
are covered with plastic sheathes to keep them free of the concrete and allow

them to be tensioned.

The printing that looks green is solder resist. This is a material used to mask areas where you don't want solder to stick, and it basically covers everything but component pads. Without it, automated wave soldering would be impossible, since solder would bridge between pads and runs. You'd also use a whole lot more solder than necessary. I've seen a few boards that went through a wave soldering machine without solder resist, and it's not a pretty sight.

It is also helpful in protecting the circuit traces from shorts and
corrosion, although it makes board troubleshooting more difficult.

I believe it is screened on as one of the final steps in manufacturing
the empty circuit board before any components are added.

You forget that the footing has TWO dimensions; my total footing will be
about 150 feet, and it sure BETTER have longitudinal rebar or it won't
support my house!-)

>Where the Ufer technique really shines is when you have a bonded grid of
>rebar in a large slab.... slip the contractor a few extra bucks to lay
>in a bonded rebar lattice for the slab....

Won't work for (at least) TWO reasons:
1) Slabs are laid on coarse gravel to allow water and radon to
percolate to the drainage tubes; gravel won't make much of a ground!
2) Although mine won't be, slabs can be laid on thermal insulation
(usually one inch of some kind of foam); foam doesn't conduct
at all!

>>If a few inches of rebar are left sticking out OUTside the footing, what
>>keeps that rebar from corroding from contact with moist soil and thereby
>>quickly becoming useless as an electrical connection?

>Nothing. That's why a real Ufer ground requires the rebar to be
>fully jacketed in concrete.

I've received several answers, all of them describing what a Ufer ground
is, but that is NOT what I asked! I KNOW how to make a Ufer ground
(at least 20 feet of rebar in the FOOTING), but I did not know how to
bring the ground out to where it can be connected to something.

At least I didn't know at the time I posted my question. However, today
I spoke with the local code-enforcement officer and learned that Ufer
grounds are fairly common around here (he mentioned a nearby large
building now under construction that uses one) and he essentially said
"A wire is run from wherever the ground is desired into the footing forms
and tack-welded to the rebar"; thus it is a WIRE--and not rebar--which
passes through the form walls.

My thanks to all who responded to both the original question ("How can
I get the best ground in my new basement?") and to this one.

1855. Re: How CONNECT to a Ufer ground?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-28 03:12:34 UTC
From: Joe Leikhim <jleikhim@nettally.com>
Message-ID: <3D6C3FA2.748A22EC@nettally.com>
Source record: 41918

1. It is good that you can have all your circuits enter near same point. It will make single point grounding simpler. A "grounded entrance window" of ~ 1/8" thick aluminum or copper sheet with all of your lightning protectors should be installed there.

2. Don't let the bare re-bar exit the footer. It will rust and spall (break open) the concrete. Three inches of concrete must encase the re-bar. Bond the re-bar to a copper pig tail lead inside the pour as suggested below.

3. I suggested an isolated and separate copper conductor around the inside of the footer. However you can use just the rebar or both copper and re-bar. If you use the rebar it should be tightly tied with iron wire at each junction. A purist may suggest arc welding the rebar at major junctions, however it is difficult to do this (from experience) and some say it weakens the rebar. To electrically and mechanically bond the rebar to the copper pig tail lead, I would suggest getting stainless steel clamps such as those used for water hoses and use to bind the copper conductor(s) to the rebar.

Ideally the connection joint would be Iron re-bar to Stainless Steel to Copper with a Stainless steel clamp for mechanical connection. You could take apart a wider hose clamp and cut up a section to use as an interface around the re-bar before clamping the copper wire.

Use a sander or grinder to cut through the oxide and grease on the rebar first. Clamp all together with the hose clamp and finally coat the junction with de-oxit compound (I used the stuff to spray on battery terminals) and coat the junction with rubberized cloth electrical tape and coat liberally with roofing tar to waterproof. Make several copper to re-bar bonds to ensure redundancy in the event something breaks or corrodes.

As a note to above, I found some electrolytic action (very small measured electrical potential) between separately terminated copper conductor and iron re-bar ground systems in my foundation. I cannot comment on the long term effect of this. I believe PolyPhazer has published a report on Ufer ground systems that may offer more insight.

>> and a 20VDC/10A output. This could be used to power the driver for
>> the 845.

That'll work.

>>
>> - the second one is not regulated and uses a 3B24 regulator tube.

The 3B24 is not a regulator tube. It's a high-voltage low-current vacuum
rectifier. The fact that there is only one indicates a half-wave rectifier
circuit.

>> I
>> was able to measure up to 1000 VDC with about 40% on the Variac. My
>> multimeter is only rated to 1000VDC :-(The capcitor following the
>> rectifier is rated @ 2000VDC. The markings on the transformer are:
>> M-7467114
>> GE CO

>> Does anyone have the specs for this tranformer?
>>
>> With one transformer putting out in excess of 1000 VDC and the other
>> with a 20VAC/10A output, can I use it with an 845?
>>

I think this power supply was meant for an oscilloscope or for a radar unit. The 2000 volt supply is low current and probably not adequate fpr the current demand of the 845.

Yes, it's the March 2001 issue of QST, on page 37, "The Warbler --
A Simple PSK31 Transceiver for 80 Meters", by Dave Benson and
George Heron. I dug up the article when I first saw this thread,
then just didn't get around to posting.

It certainly is simple, trading duplication (they use separate
crystal filters for both transmit and receive) for simplicity
no fussing with a lot of switching between RX and TX).
It a direct conversion transceiver, with the crystal filters
right on the operating system; in this case they use 3.58MHz
subcarrier crystals for the ladder filters.

For HF, the lead inductance shouldn't be terrible. But obviously, don't use standard wirewound power resistors. Watch the tolerances, too; one 10%-low resistor in the bunch will pop quickly, making very little difference in resistance (52.6 ohms) but now spreading 200 watts over "190 watts of resistors".

Josh - there's no magic here, but there are some things to be careful of.

Many higher power resistors are inductive, you need resistors that have a very small inductance at HF - and be sure it's at HF. For example, Radio Shack sells some "non-inductive" resistors for audio use, but they exhibit significant inductance at RF. This will cause your dummy load to exhibit some surprising impedance, certainly not 50 ohms.

As if that's not enough, you need to wire them together in such a way as to not add your own inductance. At 80 meters, you can probably be pretty sloppy and not have a problem. But at 10 meters, you will need to think about how you arrange those resistors to keep the lead inductance down.

Finally, there is the issue of heat. A 10 watt resistor won't stand 10 watts if it can't cool itself because it's surrounded by other 10 watt resistors trying to cool themselves.

So sure, you can build your own dummy load, and it really isn't hard, but you do need to think about it a little. If you just throw together twenty resistors chances are you'll have a problem.

..

1869. Linear PA without output filters?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-28 17:29:23 UTC
From: "Sverre Holm (LA3ZA)" <la3za@qsl.net>
Message-ID: <TL7b9.14960$sR2.274418@news4.ulv.nextra.no>
Source record: 41931

Output power amplifiers seem always to require output lowpass filters in order to meet FCC and other PTT's requirements saying "The mean power of any spurious emission from a station transmitter or external RF power amplifier transmitting on a frequency below 30 MHz must not exceed 50 mW and must be at least 40 dB below the mean power of the fundamental emission. "

Now, 40 dB corresponds to a voltage ratio of 1:100, i.e. maximum 1% total harmonics distortion (THD). However, audio power amplifiers are regularly made with THD specs of 0.1 or 0.01% - and of course there are no output filters.

My question is: why can't one build an HF PA that meets these specs - without filters?

I can think of the following answers:
- If one only used the PA more conservatively, say at only 25% of its rated maximum, it would be OK without filters.
- If you used a higher bias, i.e. move the class AB amplifier closer to class A, and allowed more dissipation, it would be OK.

I would be very interested in the opinions and experiences of this group on this question.

Hi,
i've used various resistor
and, of course, no-inductive one are the best;
but you can use common resistor in parallel (the more in parallel, the
better is)
to make parasitic inductance lower;
take a look here were there's a table with some measure made with my MFJ259

1871. Re: Coax cable question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-28 17:39:17 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D6D0AC5.3030409@eznec.com>
Source record: 41934

No.

From the _ARRL Antenna Book_, the characteristic impedance of coax is:

Z0 = [138/sqrt(epsilon)] * log(D/d)

where
epsilon = dielectric constant of insulator (2.3 for PE)
D = inner diameter of shield
d = diameter of center conductor

so with polyethylene insulation, the ratio of shield to center conductor diameter would have to be 1980:1. 300 ohm coax the size of RG-8 or RG-213 (0.285" core inner dia) would have a center conductor diameter of 0.000144 inches (0.00365 mm), or about AWG 67.

Even if you could construct some (good luck!), it would be terribly lossy.

While it might be possiable to build an amp that is class A and meet the specificiations you have to remember that if it is built for a kilowatt output then you will also be dissiapating atleast that much on the plate of the tube , or would that be 2 KW as the efficiency will be around 35 % if I am thinking right. That is a lot of heat to get rid of and a big power bill and the components have to be a lot heaver and expensive.

It is easier and cheaper to go to class AB or B and then filter the output.

There have been a zillion articles written on this subject. Check the ARRL handbook,
or about any issue of any ham magazine.

Short answer is, "what do you want to do with it?"
If all you want to do is see if you're getting output, a 120V light bulb will do.
If you want to make measurements, you need a resistor.
If you want to make measurements that you trust, you need a resistor you can trust.

The higher you go in frequency, the worse your problem becomes. AT HF, it's certainly
possible to cobble together a bunch of resistors, but it's not trivial. The equipment
you need to do it right will cost you WAY more than a real dummy load.

Inductance is your enemy. You need non-inductive resistors. Wire-wound will NOT do.
Power ratings are based on some estimate of heat sinking. For wire lead resistors,
that usually means soldered into a ground plane. IF you bundle a bunch together,
they will get too hot at rated power. Different types of resistors handle short term overloads
better. Carbon composition are pretty good at that, so if you only need to power it
for a few seconds at a time, you can get by with fewer resistors and a big fan or an oil bath.

Go to a swapmeet and buy a dummy load. Unless you already have the non-inductive
resistors, a swapmeet cantenna will be much cheaper.
Take your meter and measure it before you pay.
I don't know of any failure modes that would cause the dummy load to fail at RF and still
check good with an ohmmeter. Again, if you don't need accurate measurements you
can get by with a resistor that's a few ohms either way of 50. But you shouldn't pay much
for it. There are a LOT of BAD dummy loads for sale at swapmeets.

Josh...
Just my 2 pence worth, but...
20 years ago I made a dummy load thus.
Twenty 1k 2 watt carbon resistors, 3 inches of RG11, two pieces of copper clad board cut into 2 inch circles with one inch holes on the center.
The two rings were drilled with twenty holes and the resistors soldered between the two.
One end was soldered to the inner conductor of the RG11 which was run up the center and at the other end, the braid was soldered.
A suitable 50 ohm connector was then fitted.
This was used at low power on a homebrew 10 m rig with no ill effects and on literally hundreds of CB rigs for tuning.
I give this recipie only as a guide as to what may be possible, but no guarentees.
Good luck and cheers.

Interesting.

That is the opposite advice from what I have been given to
understand. Copper inside of concrete does not do well. Steel does
much better, and it is usually suggested around here (southern
Idaho) to bring out the rebar.

> stainless steel clamps such as those used for water hoses and use to bind the
> copper conductor(s) to the rebar.

Copper and steel touching will lead to galvanic corrosion. In the
wet alkaline environment of concrete, this corrosion will be
accelerated. Not a good idea.

> Ideally the connection joint would be Iron re-bar to Stainless Steel to Copper
> with a Stainless steel clamp for mechanical connection. You could take apart a

That would be better.

> Use a sander or grinder to cut through the oxide and grease on the rebar first.

Good idea.

> Clamp all together with the hose clamp and finally coat the junction with de-oxit

Or rather coat the components with de-oxit and then assemble.
Contact pressure will suffice to make a connection thru the de-oxit
and the grease will seal against most corrosion, for awhile.

Good point about the impedance matching, but say that you could use a 100 V power supply, then the absolute max could be P = (100/1.4)^2 / 50 = 100 W

Of course here the audio amplifiers have an advantage in that they use a 4 or 8 ohm load. The same calculation would give 28 V supply for 100 W into 4 ohms. But class A is only rarely used in audio, usually class AB gives distortion down into the 0.01 % range. It is easy to measure so I don't think there is too much cheating there.

Would a 1.8 - 30 MHz PA running from say 120-150 V power supply be impractical? - of course running class AB, not class A. What I am trying to get at is if one could trade off all the bandswitching on the output of a PA by using higher supply voltage, more expensive output transistors etc.

I've seen a high impedance cable of small diameter though not strictly
coax, the centre conducter was a very fine coil, I think it was used
on mf frequencies, very lossy of course.

On second thought, you don't need the output filters for impedance transformation, only the broadband output transformer - it must be there anyway in order to combine the outputs from the two transistors that form the push-pull output stage.

So, yes it is possible to generate 100 W from a 12 V supply without output filters. Usually the filters are 50 ohms in and 50 ohms out anyway.

All I want to do is to look at the design of HF PA's with fresh eyes, maybe the kind of transistors, power supplies etc required have become cheaper today than they used to be so the trade-offs also are different - making it possible to meet the spurious output specs without filters and bandswitching on the output?

What you're describing sounds like a delay line. Tektronix made
differential oscilloscope delay lines for lower-frequency scopes by
winding two fine wires in a helix, with the two helices in opposite
directions. As I recall, the differential impedance was around 100 ohms.
I'd expect the common mode impedance to be somewhere around 70 or 80,
although it wasn't of much interest.

About the highest impedance coax I've seen is the stuff they use, or
used to use, for car radios. I'd guess this stuff at a bit more than 100
ohms, but somewhat variable since the center conductor is free to flop
around in the polyethylene shell.

There is not very much problems in getting the THD down to those
figures at 1 kHz with plenty of negative feedback.

While I have seen some preamplifiers with good strong signal handling,
I have not seen RF power amplifiers with negative feedback. I just
wonder, how an RF power amplifier with a lot of negative feedback
would behave, if a mismatched load (antenna) is connected to the
amplifier output. You might end up with some stability problems.

>Is there such an item as 300 ohm coax cable?

Certainly not as a simple unbalanced cable, since the inner conductor
would be very thin.

However, balanced 300 ohm cables have been used for TV reception. In
these, two coaxial lines are running side by side or you could think
about it as a shielded twin lead.

1888. Sidetone and other oscillators, what are they for?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-29 00:19:50 UTC
From: vshah101@aol.com
Message-ID: <20020828201950.28641.00002863@mb-mn.aol.com>
Source record: 41851

I have some oscillator questions.

First what is a sidetone oscillator? I saw this in a block diagram of a CW transceiver but do not know what it does. Is the sidetone oscillator audio frequency or rf frequency? Why is the sidetone oscillator applied to the receiver audio section and not to the receiver mixer. What does it mean when a CW receiver does not have a Sidetone Oscillator. Is this possible? What effect does this have on the reception or decoding of the signal?

Also, what is a Beat Frequency Oscillator? I know this is rf frequency, close to the rf input frequency. What does the Beat Frequency Oscillator do? If the frequency is off, what would this do?

Also, what is a Private Line? (No, I have not used this feature yet). If a repeater has a private line audio frequency, how do I access the repeater's frequency? Do I have to turn on some switch? Lets say the carrier is frequency modulated. Is private line amplitude modulated over this carrier or frequency modulated on the carrier?

FA - E-Bay

Coils for Transmitter, Receiver, Antenna. Have seen similar coils in projects in QST Magazines of equipment made years ago. There are about 6 total, of various sizes.

There is also a CRT from a Tek 533 scope for replacement or experimenting, whatever......

Sorry, too dumb to post the sites. Will have to look it up on your own. It is listed almost word for word as I've listed it here.

Thanks,

Lou/Tech@DP.NET

Source record: 41854

> First what is a sidetone oscillator?

It is an AUDIO oscillator that produces a tone that corresponds to the output signal of your transmitter. When operating CW (Morse Code) this allows you to hear with your own ears the signal (dots and dashes) that is being sent out. It is for operator convenience.

What does it mean when a CW receiver does not have a Sidetone Oscillator. Is this possible?

A sidetone is in use only when you are transmitting and has no purpose on receive.

>
> Also, what is a Beat Frequency Oscillator? I know this is rf frequency, close
> to the rf input frequency. What does the Beat Frequency Oscillator do? If the
> frequency is off, what would this do?

The BFO allows you to hear the incoming CW (Morse) signal as a tone, rather than a hiss. You can tune in CW signals with an AM radio but you won't hear the familiar tone. The BFO mixes with the incoming signal and produces this tone. The BFO must be offset from the incoming frequency in order to produce a tone and in fact the tone you hear is equal to the difference between the incoming signal and the BFO. The BFO is usually fed into the detector stage or an IF stage preceding the detector.

> Also, what is a Private Line?

Private Line (PL) is a subaudible tone that turns on the repeater. If a repeater requires a PL and you don't transmit the correct one, you will not be able to access the repeater.

If a repeater has a private line audio frequency, how do I access the repeater's
> frequency? Do I have to turn on some switch? Lets say the carrier is frequency
> modulated. Is private line amplitude modulated over this carrier or frequency
> modulated on the carrier?

The PL tone is fed in as audio, just like your voice, and frequency modulates your radio's transmitted carrier. Most recently made FM transceivers have a provision for inserting PL tones when you program in the repeater's frequency and will store the PL tone in memory along with the frequency. Older radios can use an add on PL board or module but usually

you have to change the switch settings on the PL unit when you change repeaters.

There are MOSFET devices rated for 100 - 120 volts, usually used in medical applications.

The problems that I have seen in these package designs is that the surface area is inadequate for efficient heat transfer to the heat sink.

w9gb
Greg

PS Guess no one reads Helge Granberg, W7SE's (sk) Motorola work anymore.

I think you hit on the main difference between Audio and RF power
amplifiers: negative feedback. This is probably where the difference between
0.01% and >1% distortion lies.

The problem with RF amplifiers must be to have a controlled phase response
to ensure stability over the whole frequency range. The trend in audio is to
use more local feedback and less global feedback. Applied to RF that could
mean e.g. small unbypassed resistors in the emitter.

Maybe an RF PA with less gain per stage due to feedback and more stages
would have less distortion?

Source record: 41860

Hi.

It's all about simplicity mostly I think, keep it simple - is a general rule in electronics, the simpler something is the less to go wrong and the cheaper it is, and using passive components is mostly more reliable than using semiconductors, although I've seen a few caps and resistors go in my time - usually though due to not being beefy enough for the job.

But ... that doesn't mean to say the home user has to do that though, I'd say go for it myself, come up with a PA design that is as linear as possible, for that I fully expect you'll need to use negative feedback, transistors are simply not linear and in say a push-pull or totem pole arrangement you normally have switching going between transistors (as each takes a turn at driving the load).

The problem with negative feedback in RF amplifiers the way I see it is prolly going to be the fact that you'll need to use devices that are normally used at much higher frequencies in order for negative feedback to work properly and respond quickly as you go thru the sine wave so is prolly going to cost you more, which is no bad thing really if cost is not the prime concern.

Their are some nice op-amps around these days don't forget that work in the 100's of MHz region, I'm sure you could make use of them in the pre stages somewhere.

Anyone else agree ?

Go for it ! :)

Clive

Hello Joshua,

Look at the one I made: http://www.qsl.net/ct2gqv/dummy.html
Handles about 50W from transceiver (in AM mode) and 100W SSB for about
3-4 minutes without overheating to much.
Next step is to fill the can with OIL to dissipate better.
Good from 1 to 30Mhz but very bad at 144Mhz (probably because of
resistor nature), strange is that at 440Mhz works fine (eg: low SWR)

Regards,

Ricardo Martins / CT2GQV

=====
Many commercial rigs from the 1970-80s run nominally 100 W RF from 2x
6146 in parallel driven by a 12BY7A.
Your 5W drive would be excellent if not slightly too much to drive the 12BY7
and hence the 2 x 4146
Since many of the original rigs were not designed for the WARC bands
(although my Yaesu FT901DM using the same valves is),you 'might' have to
modify the output inductor of the 12BY7A ,where a grid-dipper would come
handy.
Matching the QRP transmitter to the 12BY7A input could probably be best done
by a fixed bias for linear operation and capacitive coupling to a say 200
Ohms input resistor which can then be matched to the QRP rig via a small
T50-2 or larger toroidal balun 4:1 or a smilar balun made of a ferrite rod
antenna (piece of it)
With the 17m band only covering 100 KHz there would probably no requirement
for any adjustment to the power amp once setup.

Feedback has been used in RF and IF amplifiers to get a good signal
handling capacity with moderate bias current. For instance the article
"A High-Dynamic-Range MF/HF Receiver Front End" by Jacob Makhinson
N6NWP (QST February 1993 starting at page 23) describes push-pull
preamplifiers with feedback running at 2x25mA or 2x40mA.

These might give some ideas for power amplifier design.

1909. Varicap tuned LW/MW loops

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-29 21:16:58 UTC
From: Richard Daventry <nearlynews_email@ntlworld.com>
Message-ID: <akm2qo$1jmt0b$1@ID-150848.news.dfncis.de>
Source record: 41872

Surprisingly I only found one design on the whole of the web at:

http://www.carcanada.net/dx/RTL.html

If one were to seperate the coupling loop from the varicap control lines, would 75 Ohm twin or even twin bellwire be good to use, feeding a balun at the rx end? Also, would it be okay to use a single 2 core screened cable to the varicap? Are varicaps unreasonably lossy? It seems odd that there is only one design seeing that varicaps are eminetly suitable for remote tuning.

I can hardly read the schematic, anyone tell what C1 to C6 values are? 0.1 uF? Apparantly article published in Practical Wireless Oct. 1984, which I do not have a copy of. :c(TIA. Rich.

1910. FS Teflon Wire

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-29 21:21:12 UTC
From: James Skalski <jskalski@bellatlantic.net>
Message-ID: <3D6E9EEF.30009@bellatlantic.net>
Source record: 41873

I have some Silver plated stranded teflon wire for sale. (The Gud Stuff)

Wire will be shipped via UPS and shipping is included. I will need a street address not a PO Box to ship.

On Colors - No solids, No special requests. It is packaged already. To do otherwise would raise the cost considerably in terms of time and manpower.

On wire Gauge. Most of the wire is 22AWG, Some is 24AWG. There might be some 26AWG. No other sizes are available here. You might try Newark.

The wire is excellent. It has been used for boatanchor repairs, new construction, Mars Probes, model rockets, robotics, Manhattan construction, people have used it for portable antennas, and some permanent stealth types I have heard but have not confirmed that birds slide right off the stuff.

It has high reliability and solders extremely well. The teflon will not melt or shrink when you solder the wire. Unless you use a blow torch and raise the temp above 200 degrees C.

The price is $30 for one 1000' roll including UPS shipping. This is for a Continental USA address. (About one third of this cost is for the UPS and shipping container.

Payable by Money order, Check or Paypal.
Paypal address is n2go@arrl.net
Confirm availability before sending payment.

If you can use larger quantities, the price is $20 per 1000' roll plus the UPS costs. The savings reflect the ups rate sheet.after 10 pounds the price goes up slowly.Larger quantities can be supplied in a variety of colors but again no specific color choices and no solid colors.

Jim n2go

I built the one pictured in the ARRL Handbook. I don't remember the year but I could look it up if you need to know. It was very simple it just took carbon resistors, of an appropriate value and parrelleld them by soldering them between two pieces of circuit board. You can work it out by estimating the wattage of a single resistor then using X number of them to achieve a Y wattage rating. Plug in the numbers to the resistors in parrllel formula and you can find the value of each one. Next is the hard part. Scrounge around the surplus stores until you find a handfull and make up the load. Mine worked well 160-10 although it ran cooler when I cooled it with a small muffin fan and even cooler when I submersed it in some (Silicone) Oil left over from a Xerox Machine. I can't understand why my wife thinks I'm crazy though?

The biggest problem I have found with trying to remotely locate a loop
is the feedline pickup. Even a few feet of wire can ruin an otherwise
good setup. Coax obviously would load the circuit. I don't know a good
answer but he seems to have a solution.
I think .05 or .1 caps would be suitable. It says 0uf on the
schematic?!?

I wonder then if the coupling loop should be connected with balanced twin coax sheathed cable. Probably. That would not be unsimilar to his set-up, except that he uses two seperate coax lines instead of twin wires in a coax sheath. And of course he sends the DC to varicap down these lines.

What are the advantages and disadvantages of using a "large" frequency deviation for an FM channel (say
+/-75kHz) over a "small" freq deviation (say +/- 6kHz)? I can't see how this would affect message signal
bandwidth. Thanks for the help. I really appreciate it.

Pretty much everyone mentioned that you'll have trouble using
wirewound resistors, which is true. Even if you parallel a bunch,
above some frequency it won't help because they have so much
inductance and distributed capacitance that they will be
self-resonant. There are some other tricks you can play however. If
you can get a long piece of RG-58 cheap (like some old lan cable
perhaps), you'll get reasonably close to 50 ohms load no matter what
you put at the other end. The down side is you'll need several
hundred feet of it for that to be effective at 3.5MHz, because the
coax loss is pretty low there. In this case, loss (in the line) is
your friend! Another thing you can do, if you have a tuner, is use
the tuner to tune out the reactance (and the resistance mismatch) of
whatever load you build. In fact, if your load is simply inductive
because of the coiled wire in wirewound resistors, you can tune that
out with a series capacitor. (Alas, there seem to be a lot fewer air
variables kicking about in junque boxes these days...) You're liable
to find that only works at the low end of the HF band because of the
self-resonance effects. I just measured a pair of parallel 100 ohm 5W
wirewounds, and found them to degrade rapidly as a load above 14MHz.
Larger wirewounds would likely be worse. On the other hand, I
measured a 51 ohm metal oxide 2 watt resistor ("very short" leads),
and it would be very servicable as a dummy load even at 440MHz, where
it's 55.87+j17.61 ohms (per a precision RF component analyzer...),
giving an SWR in a 50-ohm system of 1.42:1. At 146MHz, it's
51.43+j5.95, SWR=1.13:1. Interesting thing about metal oxides is that
they seem to be able to stand rather incredible power overloads, and
one could probably make quite a respectable load with twenty or so of
them dropped into some oil. Best to think carefully about how to wire
them up to avoid parasitic inductance and capacitance.

Cheers,
Tom

> Is there such an item as 300 ohm coax cable?

If you want it with a straight center conductor, then the d/D ratio
must be 1:148.4, and that's assuming air dielectric. A very light
foam wouldn't make it too much worse, but still, you'd need to be
using a 40-guage center conductor in a nearly half-inch diameter outer
conductor. I figured the loss would be awful, but my calc tells me
that it wouldn't be so bad...about 1.5dB/100 feet at 10MHz, which
isn't much different from RG-58. (Did I make an arithmetic error??
Don't think so, but maybe.)

So yes, one _could_ make such a line, but why??

As others mentioned, if you make the center conductor a helix, you can
make darned near any impedance line you'd like. It won't behave
exactly like standard coax, though, with respect to propagation
velocity versus frequency...the turn-to-turn capacitance will do funny
things.

Cheers,
Tom

1922. Re: FM Deviation

All else being equal, increasing the deviation will increase the bandwidth, and if properly received, will also increase the signal/noise ratio. That's the trade: bandwidth for S/N ratio.

FM analysis for anything other than simple tone modulation is very complex -- tone modulation is complex enough --, so for tone modulation:

The modulation index m = fd / fm

where
fd = peak deviation
fm = modulation frequency

For very narrowband FM (m << 1), bandwidth ~ 2*fm. For wideband FM (m >> 1), bandwidth ~ 2*fd, and for m ~ 1 (typical "narrowband" FM), bandwidth ~ 2*(fd + fm). If you're frequency modulating with, say, a 3 kHz tone, m = 2 for fd = 6 kHz, so the bandwidth is about 18 kHz. For 75 kHz deviation, m = 25, so the bandwidth is ~ 150 kHz. The improvement in S/N ratio depends on the modulation index and whether preemphasis is used, but in wideband systems it increases as the square of the deviation.

The reason there are several equations is that frequency modulation of any amount actually creates an infinite number of sidebands on both sides of the carrier, spaced from the carrier at each harmonic of the modulating frequency and having amplitudes described by Bessel functions. The bandwidth is defined by deciding which sidebands contain significant energy, and declaring the bandwidth to be the space these occupy.

You'll find a brief discussion of this in the _ARRL Handbook. For more detail, see Terman's _Radio Engineering_, or a communications text such as Carlson's _Communications Systems_.

It affects the RF bandwidth (do a web search for "carson's law fm bandwidth") but not the message signal bandwidth, as you point out.

But the real reason has to do with the improved signal to noise ratio that can be achieved with a wide deviation.

You could read a textbook to find out why, or search the web for articles like this one:
http://groups.google.com/groups?selm=37733912.21210660%40newshost&rnum=2

FM with a large modulation index is typically used in situations,
where a high _baseband_ SNR is required.

When receiving broadcast quality FM signals, audio signal to noise ratios of 50-70 dB are typically achieved. To achieve similar audio SNR using AM, the signal at the receiver antenna terminal would also have to be 50-70 dB stronger than the noise. However, when using wide FM, the antenna signal only needs to be, say, 40-60 dB stronger than the noise, thus the transmitter power can be 10 dB less than in the AM case. Thus, if a 50 kW FM transmitter is needed to get a specific audio SNR, a 500 kW AM transmitter would be required to get the same audio SNR. The "FM advantage" or the ratio between the audio SNR and the antenna SNR varies with the modulation index used, but 10 dB is here used as an example.

Thus, this is an exchange between bandwidth and power.

When the antenna signal power goes down, the FM receiver gets saturated by noise at the FM-threshould and the FM-advantage is quickly lost and eventually wide-FM is worse than narrow-FM at very low levels.

Thus, if the target audio SNR is in the 20-30 dB, such as in communication class audio (radio telephony), there is no point of using wide-FM, since it would be operating near or below the FM-treshold anyway.

Even wide-FM can not provide audio SNR in the 70 to 100 dB range, since this would need huge transmitter powers and extremely wide bandwidths. The only way to reach such SNRs is to use digital audio. By adding one bit to the audio sample will increase the audio SNR by 6 dB, but will only increase the required transmitter power and bandwidth by less than 10 %. Thus, this is a very effective exchange between bandwidth and power. However, uncompressed digital audio has an even worse threshold, when using low signal to noise ratios.

Paul

Oh, dear! There are quite a few designs on the web that I'm aware of.
Have you not found Lyle Kohler's site? Have a look for it.

Darn, I really should find some more round tuits. I did a
modification of one design Lyle has posted, which offers very stable
remote tuning and power feed over the same feedline that comes back
from the antenna. Just hook the antenna to the preamp, and a feedline
between the preamp and the power supply/control box, and you're set.

The clearest explanation I've seen of the need for balance in a small
loop is in King, Mimno and Wing, "Transmission Lines, Antennas and
Waveguides." There should be no particular problem using coax as a
feedline, IF you keep your wits about you with respect to balance.
Balance is critical! The advantage of a "shielded" loop is that the
shield acts as the antenna, and it can be made very symmetrical. It's
inherently easy to feed coaxially, actually.

Cheers,
Tom

A large modulation index improves capture ratio and FM "quieting" in a FM system. This threshold effect means that a signal with a large modulation index can have a higher baseband SNR (Signal to Noise Ratio) than its raw CNR (Carrier to Noise Ratio) in the presence of noise and interference. This gives relatively high quality audio right out to the edge of coverage. In other words, you have a good signal right out to near the point where you have no copyable signal. This is why FM broadcast uses it. The obvious downside is that you can't pack many signals in a given hunk of spectrum.

A signal with a modulation index of 1 behaves more like an AM signal in that there is very little threshold effect. As the CNR declines, so does the SNR, almost in lock step. But since the occupied bandwidth is less, the CNR can be better in the first place (narrower IF filtering), so ultimate range may be better than for a FM signal with a high modulation index, though the signal gets progressively noisier as range increases. You can also pack more signals in a given hunk of spectrum, thanks to each signal being narrower. This is generally a better tradeoff for communications quality speech. Hence this is why it is used for 2-way and amateur systems.

Another factor is that in the early days of VHF/UHF it was difficult to maintain good frequency accuracy and stability, and a wider signal is more forgiving with respect to tuning errors. Thus most early systems used large deviations for this reason too.

Also, a FM modulator was (usually) a single receiving-type tube, rather than
a set of power tubes at least as big as the final RF amplifier and drawing
about as much power. Important for mobile applications.

1931. Use GFI as an emergency power cut-off?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-30 17:51:09 UTC
From: mcalhoun@ksu.edu
Message-ID: <akobad$5aa@unix2.cc.ksu.edu>
Source record: 41894

I've been convinced to put a bathroom in our soon-to-be-built basement. Unfortunately, the floor of the basement is 4-5 feet BELOW the entrance to our sewer line, so we'll also have to install a "sump" for sewage, and that, of course, necessitates the use of a sewage-capable sump pump. (This is all in addition to the usual sump and pump for water that makes its way down to the basement footings after a rain.) FWIW, the sewage sump supposedly will have a capacity of about 25 gallons, although I've not yet seen it.

My plumber says that, although it may last 15 years, that sewage-capable pump WILL eventually fail, so I intend to also install an extra float-activated switch to trigger an alarm when the level in the sump pit rises above the maximum level that it should. I have no idea at what level the sewage pump should normally engage, but, for the sake of the following example, let's assume the "normal" maximum level is 10 gallons and my "emergency" monitor triggers at 15 gallons.

Years of experience have convinced me that Murphy's first law ("Whatever can go wrong will!") applies in my household, so I can forsee the following failure mode:

Suppose it is laundry day. According to the manual, our washing machine uses 38 gallons of water for a regular load. Also suppose that, at the instant the aforementioned sewage pump quits, a bit of "stuff" is caught in the one-way valve which normally keeps "stuff" from the upstairs floors from making its way to the basement instead of going out the sewer line as it should. The pump probably quit at start-up time, so the pit now contains about 10 gallons of stuff.

Add the washer's 38 gallons, and, even if a VERY LOUD alarm is triggered, by the time someone realizes what's happening, there's going to be LOTS of water (and other "stuff") overflowing onto the basement floor!

Obviously the sump alarm needs to turn the washing machine off automagically. I've never looked inside a GFI (Ground Fault Interrupter), but I wonder if one can be homebrewed into a shut-off relay triggered in some way by the sump alarm. Do any of you electrical homebrewers know just what's in one of those GFI boxes often seen in bathrooms? (I'd go buy one and disect it, but my workshop and all of its tools are currently packed away waiting for the new basement!)

A GFI senses differences in current between hot and neutral. If there is
no fault, they should be the same. When there's a fault, the currents begin
to differ. The GFI will trip when the difference exceeds about 4 mA.

It'd be tricky to safely use the GFI as an appliance relay, though. Simpler to
just use an X10 appliance module for the washer, and an X10 contact closure
triggered transmitter module (burglar alarm module) to activate it.

One more thing, chiming in on Doug's comments: The FM modulation can
indeed be done at low power stages, and the subsequent amplification needs
only a limited form of 'linearity' when compared with low level AM modulation.
(FM modulation can be done at higher powers, but tends to have limited
deviation because of the PM vs. effective FM being done in an oscillator.)

The sum total of low power modulation of FM, and the need for fewer kinds
of linearity than amplication of AM signals (if done at low power), make FM
potentially more desirable for portable usage power needs.

I've never run across an FM transmitter that didn't perform the modulation at the low level stages. Often Phase Modulation is actually used (the actual output is the same as an FM signal) because it is done in a separate stage and doesn't impact the stability of the oscillator. Since an FM signal changes only in frequency and not in amplitude, the following amplifier stages can be class C. Class C amplifiers are more efficient than the class AB amplifies needed to maintain the linearity needed for AM or SSB.

Actually, this is not exactly true. In true FM, the modulation vector is independent of frequency. In PM, it is not. However, a simple RC network can usually "correct" PM to make it look like FM - at least for voice frequencies.

Worth noting that common application of FM for narrowband voice applications applies a nominal 6dB of preemphasis across (essentially) the entire modulation passband. Applied accurately to single tone modulation, this results in deviation proportional to modulating frequency and therefore modulation index being independent of modulating frequency (which characterises PM), and the noise improvement is not as described for FM. (This is not to comment on the technique used by the modulator, but on the characteristic of the modulated signal to air.)

It is usually done the other way around. True FM modulation gives a
flat modulation (deviation)
response with modulation frequency. PM gives a response that in effect
increases the deviation
with modulation frequency. You can think of PM as having it's own
built in pre emphasis. To
use a true FM transmitter in the same system, pre emphasis is added
to the FM transmitter to
match that of the PM transmitters.

Pre emphasis is desired for noise reduction at the receive end. This
allows the receiver to roll
the high frequency response off in it's audio stages thus reducing
high frequency noise.

It is interesting to note that FM has a much better signal to noise
ratio than AM but as the signal
starts to go into the noise it gets lost very quickly. AM is superior
for high noise to signal
performance. AM can be copied when FM can not. If I remember right
there is a 6 db
advantage of AM over FM.
There is some interesting discussion on this in some of the older
handbooks.

Yes, an interesting effect is that at poor S/N ratios, the modulation on an FM signal ends up getting approximately multiplied by the noise, rather than added as in AM. So extreme distortion occurs when the S/N ratio of an FM signal deteriorates. I've been told that this is the reason that aircraft radio is still AM -- so a person can still be understood even when the signal is marginal.

The FM capture effect, where a louder signal completely masks a weaker one, might also be a disadvantage in some emergency situations. With AM, you can at least usually tell when more than one station is trying to transmit at once.

Have the sump switch/alarm also complete a 10k circuit between the 'hot and ground' of the GFI circuit run. This will trip the "Ground Fault Interrupt" breaker the washer is on. Make sure the alarm is powered by a different circuit breaker.

I wouldn't mess with a GFCI, whatever you do to trigger it probably would not pass an electrical inspection. I think there is at least one better solution:

Assuming that the only danger is water from sources within the house (you might want a backflow valve on the sewer line to keep the sewer from dumping into the house), consider an electrically operated valve on the main water line. The valve could be configured so that as long as electrical power (low 24 VAC) is present, the valve is wide open. Wire the overflow switch so that the power to the water main valve is interrupted at high water level. In the same way, an electrical power failure will close the valve preventing flooding due to the sewage lift pump's inability to run. You might consider a battery operated sump pump as a back up to your rainwater sump pump as power failures often accompany heavy rain.

Finally try to plumb the system (floor grade) so that a lift pump overflow will run into the rainwater sump pump before going anywhere else (environmentalists will hate this) in the basement.

Also keep in mind that the water heater may need to be shut off if the water supply fails. If the water heater is in the basement with no risk of siphoning dry, this may not be an issue.

Both are significant advantages of AM over FM. If you fly the Los Angeles basin, or near any busy airport, you'll find many transmissions from the control tower are stepped on by another pilot. With AM, you can tell the controller you missed his transmission. With FM, you might never know.

Of course, flying in the Los Angeles basin might be considered an emergency situation by some pilots:)

1947. Evaluating ATU efficiency

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-08-31 07:55:15 UTC
From: John Fletcher <John@kanga.demon.co.uk>
Message-ID: <nGrg3AAjZHc9Ew52@kanga.demon.co.uk>
Source record: 41813

Hi all!

When I get the time... I want to home-brew an ATU for QRP use, probably of the Z-match type. Because it's for QRP I want it to be efficient. It will be used with short or random wires from temporary locations (campsites, hotel rooms and such). I want to do some comparisons of ATUs using different components, different core mixes, air-spaced and polyvaricon tuning caps. Is the following a good approach to comparing efficiency?

Transmitter connected to calibrated bi-directional wattmeter connected to ATU-under-test connected to complex load made from R and C or R and L representing a random wire.

Set transmitter output power to a reference level (say, 1 watt).

Adjust ATU to give best match.

Measure voltage across resistive part of load using a 'scope. Record it.

Repeat this with different values in the load and different components in the ATU. Highest voltage across the resistive part of the load equals highest efficiency.

Am I on the right lines or is there more to it than this?

Thanks for any comments,

John G4EDX

Myron,

It sounds to me like you are way over-engineering this problem. I have (what sounds like) the exact same arrangement in my home - all plumbing is on the first and second floors (including the laundry) but I added a lav, shower and utility tub in the basement. Lav and utility tub share a common sewage crock and pump in the basement floor, which must be pumped up, through a one-way valve, through a loop OVER and down into the house main sewage line and eventually out into the septic system. The crock has an alarm on it to notify me when the pump has failed to operate. (hasn't happened yet)

For you to experience the problem you describe, several simultaneous failures would have to occur - including the fact that the rest of your domestic waste plumbing would have to back-up and fill so that the laundry run-off would drain down into the crock. [keep in mind that the "T" from the house line to the crock does not point down, it points up - meaning that your septic field would also have to be backed up in addition to the failed one-way valve and the failed pump.]

If you worry about events that require multiple simultaneous causes... I'd suggest that you have your builder put a privy out in the backyard, and simply avoid all running-water-related possibilities! ;-)

And, what does this have to do with ham radio? Let me guess - the Ham Shack will also be down in that basement and if the flooding reached the top of the desk you would have some unfashionable two-tone equipment! ... now I understand! ;-)))

The safer way to do it would be to install a box with a relay near the washer rather than fooling with the GFI device. Let the alarm circuit hold the power relay closed to keep power on the washer. Open power to the relay coil and the washer turns off.

By the way, I've had a septic pump with an alarm installed for over 15 years and never had a failure (although my tank is around 500 gal as I recall).

The actual primary reason is that the whole world would have to switch from AM to FM at the same precise instant and that is an impossible task. We would have gone to FM with the rest of the world in the '50s but for the logistics problem.

Individual safety units (fire and cops) could do it one city at a time, but doing everywhere from Kalamazoo to Copenhagen at the same instant is damn near impossible. Believe me, there have been more task forces studying this one problem than anything else in aviation. There are answers, none of them cheap and all of them difficult.

That's precisely the reason why VHF-UHF Aeronautical comms is done in DSB AM
mode , and HF Aeronautical comms in SSB (also AM be it without carrier
using only 1 sideband).
I suppose SSB VHF-UHF for this service would be no advantage over DSB in
view of line of sight propagation .

I think the reason it was done that way is because AM was the standard at the time it was done. The "primary" reason it is still AM is because it would cost so much to make the switch to FM (aircraft would have to carry two radio systems, one AM and one FM until everyone was able to make the change over). All the other stuff provides some additional justification for leaving it AM.

FM also does not provide as much of a benefit for aircraft because their height generally give them good signal strength and they don't have much multi-path to deal with.

With jets flying at 300 m/s, the doppler shift would be 1 ppm, so at
120 MHz, the frequency shift would be 120 Hz and at 1 GHz a whole kHz,
thus, with SSB reception, you would have to operate the clarifier
(with twice that amount) each time the plane flew over a place.

Implementing a diversity reception system with remote receiving sites
would also be hard, since each receiver station would experience a
different doppler and combining the audio would produce strange
effects.

When using AM, the audio is recovered as the difference between the
carrier and the sideband, while both suffer (approximately) the same
doppler shift, so the sound pitch does not change.

So I take it that, if it weren't for the practical difficulty of switching from AM to FM, that aircraft radio would be FM. Weak signals would be unintelligible, and stronger signals would capture receivers. What would be the advantages over the present system that would still make it worthwhile in light of the disadvantages?

The only problem with any sort of homebrewed design is that CTCSS
tone frequencies are critical. They need to be maintained to a tolerance
of about +/- 0.75Hz.

This is, of course, not an issue if you're using a crystal
oscillator and divider chain. However, in this context, there are pre-
made solutions available at reasonable prices.

http://www.com-spec.com/ss64.htm - $28.95, and you can program it
with its DIP switch pack for any of the 64 standard tones.

http://www.hamtronics.com/ - A competing unit from HamTronics.
Available as a kit or pre-built. About $11 more expensive than the
ComSpec unit above.

Good hunting.

We in fact do have some company air-ground channels that do use FM for compatibility with existing ground units. As far as I can tell there's no practical difference in performance from an aircraft in flight because you are always dealing with pretty strong signals. The exception might be a downed aircraft in the middle of the sticks somewhere.

We also have some HF SSB units for long haul communications. The biggest issue with the HF is operator training - getting them to understand that you don't pick a 15 Mhz frequency to communicate with someone 300 miles away.

The bottom line is that I don't think FM was an option when radios were first placed into aircraft so I doubt that engineers sat around and discussed AM vs FM and picked AM as the better mode for aviation.

It's far from that complicated. If you have ever done power supply
switching or highway construction, you learn how to maintain flow
while inserting a second artery.

It requires only the installation of duplicate services on the ground
and cross-band linking. Employ a frequency raster plan with alternate
AM and NBFM. The plan has been done, the impediment is the inertia of
the GA sector to spend any money esp. on recreational/private a/c.

I also recognise the merits of AM in cases of "doubling", but AM is
prone to many effects that do not compromise FM - such as prop
modulation and the inherently worse impulse noise behaviour of AM.

I've never measured its size, but the degausing coil around the face
of a TV picture tube may be about that size, and just one such coil
should give you enough wire for LOTS of toroids!

============
AWG24 wire has a diameter of 0.020 inch = 0.51 mm which should be available
from any electrical motor rewinding workshop.
Speak nice to them and they will be giving you a few metres of wire free of
charge. Suggest you bring a calliper (US: caliper) with you .
The nearest standard metric size of wire is 0.56 mm dia
For enameled wire you might have to add 0.2mm.

Radio Shaft sells a package of 3 spools of magnet wire, one of which, if I recall, is 24. However, the wire size isn't all that critical in toroids except in cases where you are really crammed in. So if you already have some 26 or 22 I'd just go ahead and use it. You'll get a better deal, of course, mail order. But RS has the advantage that you could be winding toroids this afternoon. There's an outfit called "The Coax Connection" that has quite a range of magnet wire at reasonable prices. They tend to frequent a lot of hamfests if you're not in a terrible hurry. They do mail order, too, but I don't know if they are online.

How many American private pilots will fly over Europe or Africa ?

As long as the ground segment in a certain country has been fully
converted to AM + FM, all those planes flying in that country can use
either AM or FM. It would be natural to replace the AM radio with an
FM radio during a major overhaul of the plane. Only if you intend to
fly to a country that has not converted to AM+FM, the plane needs to
be equipped with both radios.

Anyway the aviation AM/FM debate is obsolete, since in a few years,
the debate is AM phone / digital systems.

I live in West Tennessee and we have a motor re-wind shop 30 miles from
where I live. You might try a large city. BTW, they also rewind
transformers.

Use an FX335 ic its so simple just a few componants if
its just encode you need, bit more complicated for decode
as well.
I have modded quite a few old PMR's for ctcss no problem

I've had motors rewound in Madison, Wis. and I know there are shops here in Nashville that will do it too.

(do they deal with anything small enough to use #24?)

Phase modulation is never used for wideband FM. This is because the
modulation index is huge when the audio has strong low frequency
content. E.g. M = 75kHz/20Hz = 3750 radian peak. I'd like to see a
phase modulator that can do +/- 3750 radian and still be cost and
performance competitive with a VCO.

Most cheap (and expensive!) broadcast exciters use a VCO that is
locked to a crystal using a PLL with a very low loop bandwidth. The
baseband composite stereo signal is added to the control voltage from
the PLL.
Some modern exciters use direct digital synthesis.
(So why do they still teach Armstrong's method in undergraduate
courses? Has this been used at all in the last few decades?)

Regards,
Allan.

They used to be as thick as flies in the rural parts of the Midwest. There are still plenty of signs, but my wife found out a few weeks ago, that only about one in ten of those signs is in front of a still operating shop.

Nonetheless, she only had to go a couple of miles, and we are in a part of the country where the next town is 25 miles away, so they are not so uncommon.

1982. Re: FM Deviation

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-01 16:50:08 UTC
From: Jim Weir <jim@rst-engr.com>
Message-ID: <f7g4nu81hfp3em5f2a638jn7i7aaq5rsl7@4ax.com>
Source record: 41845

In the Hamsher bible ("Communication System Engineering Handbook, first edition, 1967, page 17-13), the signal to noise ratios of wideband FM (10 kHz. dev), narrowband FM (3.3 kHz. dev), and AM 100% are compared. Down to 0.1 microvolt the narrowband FM is always a better s/n than the AM at the same input level. The crossover level for wideband FM to AM occurs at 0.2 microvolts.

Therefore, with narrowband FM, there IS no weak signal advantage and with wideband FM the advantage is so far down in the noise at the crossover (5 dB sinad) as to be negligible.

It is also true that AM has a "capture" effect. You can call it AGC effect or anything else you choose. Unless the signals are extremely close in level, one will always "step on" (damn, I hate that term) the other. Will you hear a squeal? Possibly, but not always. And, the odds of both stations starting and ending their conversations at the same exact instant is near zero. The point being, you will 99.999% know that two stations are trying to communicate with you if they are on the same frequency at the same time. If not, the general case is to wait half a minute, and if still not acknowledged, repeat your request.

As to the advantages of moving to FM, I hope it happens well after I retire. There aren't but a handful of us left in the industry that specialize in VHF-AM. I could name them on my digits without taking off my socks. It is a built-in job security that I just love.

Being serious, though, you have absolutely no idea of the hassle you go through finding components rated for AM service. SOA means a hell of a lot when your collector voltage goes double the supply on the modulation peaks. Add to that any urps caused by reflected power, and you find yourself specifying a pretty hefty device for a fairly low power transmitter. In the receiver, things are even worse. When is the last time you ever saw an AM IF strip with AGC on a chip? LM373? LM1868? And they've been out of the pipeline for twenty years. Not only that, but they were meant for crackerbox radio AM, so you wind up double-converting (with the concomitant bird and spurious problems) to get down to a point where they are usable.

FM power devices and receiver chips? The kind they use in marine and safety radios? How many boxcars full would you like tomorrow morning?

OK?

I dunno but when I took over engineering at KMEO-FM in 1964 or 1965, the transmitter had a phase modulator and, after I got the piece of junk on the air, I had FM stereo and the 67KHz subcarrier for Muzac or whatever all nicely in specification according to FCC rules and Regulations. Talk about fun. I had to work after midnight because of rules on testing and I had to chase centipedes and scorpions out of the way whenerver I wanted to put a probe on anything. BTW, KMEO-FM still exists under the same license except that KUEQ-AM, my other headache back then, is now under the KMEO license. If it is still owned by the cheapskate I worked for, the transmitters haven't changed. :-)

Check your local marine store. Shakespeare makes some marine SSB
fiberglass whips that are 23' long.

You have obviously missed the point. The only duplication necessary
during a changeover period is ON THE GROUND.

Hi!
Got in the same "trouble" when I bought the 706, so I built a couple of
paddles from scratch (wood, 2 microswitches and a few other junk parts):

http://www.qsl.net/ik1zyw/hardware/key/index.html

They're ugly looking and don't allow fast keying, but worth a try for 2$.

Then upgraded to NB6M's design, but I'm lacking of the proper tools to
cut/shape the PC board.

Hello all,

I'm thinking, for EMC prequalification purposes, of building my antennas.

I've found a good page for the logperiodic one, but can't manage to find
anything usfull for the biconic. (30MHz-200/300MHz)

Anyone can point me to good sites ?

Thank you in advance .

Fred.

> The only duplication necessary
> during a changeover period is ON THE GROUND.

That means that in an emergency one pilot cannot talk to another (one is using AM and one has changed over to FM). It also means that some will not be able to hear instructions from the tower or ATC to others or their responses (a dangerous situation). Unless frequency assignments are changed, you will also have a terrible QRM problem trying to run AM and FM on the same channel. I don't think you understand the complexity of the situation - it is far more complex than cutting over a power system.

Is there a homebrewers way to test microwave diode rings? I have an
Advantest 4113AL Spectrum Analyzer and I suspect the mixer has been blown.
I found an NEC ND587R-3C mixer diode ring. This device is smaller than a
match head with 4 leads. I don't want to take a chance on burning out these
devices if they're good so any tips on how test would be appreciated.
tnx

2016. Connecting circuit boards

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-02 20:39:36 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <3D73CD62.285B895B@alma.demon.co.uk>
Source record: 41779

I wonder if anyone has a good solution to the problems of connecting power, pots and variable capacitors to circuit boards, and interconnect between circuit boards?

It's really useful to be able to totally disconnect a circuit board from all the wires in order to remove it. For example for potentiometers I put a 3 pin header on the circuit board and then have a 3 pin plug on the leads from the pot. It's a bit of a pain to wire up the plug and leads.

A lot of RF circuits can be broken down into sub-circuits and each built on their own circuit board, possible for re-use in a later project. I have no idea what to do for the RF/VHF connections. I could use SMA/SMB/SMC sockets on both baords and short wires with plugs to make the connection, but these parts appear to be expensive and not readily available from the usual hobbiest suppliers. Apparently making the SMA/B/C plugs and leads is quite tricky.

regards...

I wrote several short articles about this in my column around 1996.
There is a searchable cumulative index at
www.ifwtech.co.uk/g3sek/in-prac

Agreed about the miniature coax connectors - these are best bought as
surplus jumper leads with connectors on at least one end.

I buy pre-fabbed SMA (male-male) cables on eBay. They're very common,
in many different lengths. Stay away from the hardline stuff, unless
you (unlike me) know how to bend it without breaking it.

SMA jacks are also very common on eBay. The project on my bench now has
ten Hammond subassemblies and counting, all with SMA interconnects (and
D-sub jacks for digital control). I've never had to make up a cable by
hand, because they're so easy to find.

I've been told it's because of the FM capture effect; i.e. two signals on
top of each other can be heard with AM, where only the stronger prevails
most of the time on FM. Ergo, no distress call goes completely unnoticed.

well the kiss method would be a second sump pump set to go on at the high mark of the first and keep it at that level while the alarm is ringing on the first sump (Murphy will tell you the first pump will fail Friday night while you are out drinking and it will be a holiday weekend ... no pumps to buy till Tuesday.) This gives you enough time to get a paycheck to replace the failed pump...without the extra lost money.

doh - REALLY?

Years back I saw a paper on how the transition could be implemented
with minimum pain, and as an experienced comms engineer I couldn't
fault it.

Unfortunately, the bits or resonse to various posts in this thread
need to be assembled in one place for better understanding. I'll do
what I can.

New FM ground services are installed on a 1:1 basis with existing AM,
with cross-linking. Ground controllers fire up both in parallel, an
air-side service activating the ground FM receiver causes the ground
AM Tx to repeat the transmiision, and vice versa. Simple example of
cross-band linking except here it is cross-mode within the same band.
And no, they don't put AM and FM on the same frequency. So a single
role (e.g. ATIS) might be 120.9AM and 128.9FM at a particular
location. I think you fellas are smart enough to fill in most of the
blanks.

There was far more in that paper, but I didn't bother to commit it all
to memory because much related to the politics and to entrenched
interests rather than technical considerations.

Agreed - there are lots of nice microwave units around that consist of modular boxes with jumpers made of SMB/flexible and SMA/hardline. If you go to a microwave meeting such units may be expensive, but when they turn up at an HF/QRP event they're practically given away.

>Stay away from the hardline stuff, unless
>you (unlike me) know how to bend it without breaking it.
>
In a word, gradually. The professionals use a miniature version of the plumber's pipe-bending jig, but you can also roll it between the bench and a cylindrical former (aka electrolytic capacitor). The trick is to press down hard and keep the semi-rigid very firmly trapped so it can't kink.

Also the copper work-hardens. The first bend is easy, but the second in the same place is much harder and the third is darn near impossible... so don't ever straighten any pre-formed jumpers until you're ready to use them, and try as much as possible to use the bends that already exist.

2028. MAX2650, any design?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-03 07:55:40 UTC
From: Paolo Cravero <fake.address@asdrubale.net>
Message-ID: <3d7461da$1@news.opennet.it>
Source record: 41791

Hi.
I have ran across the way of Maxim's MAX2650 datasheet (DC-to-uwave, +18dB, 3.9dB NF amplifier), and started wondering if such a chip could have any use for HAM purposes.

It features 50ohm IN and OUT ports, and a simple +5V supply. The sample circuit from datasheet (http://www.maxim-ic.com/quick_view2.cfm?qv_pk=1521) shows only 3 bypass capacitors: would that be enough? I am afraid that it would output lots of intermodulation products given the ultra-wide operating range, if used without input filters (am thinking of a 144MHz preamp generating 88-108MHz splatters everywhere in the RX).

Has anyone seen a HAM design somewhere with MAX2650? A google search didn't return anything.

Am I on the right way to build a simple preamp?!

73s!

I recently had the same problem. My cost-effective solution is the "F-series" satellite connectors from Farnell http://www.farnell.com, e.g. Order code 150684 (plug), 150686 (bulk-head socket). The plugs can be purchased to suit cable such as RG6, RG59, RG62 etc. The great advantage is they're a small fraction of the cost of SMA connectors. For example this plug is GBP 0.27 and the bulkhead socket is GBP 0.35 (equiv. US$ 18 cents and 23 cents respectively). I bought 10 of each for when I put my HF receiver (http://www.hanssummers.com/radio/polyphase/index.htm) into separate nicely screened modular boxes.

Next problem - what do you do about power/digital connections to screened boxes if you don't want to buy those expensive feedthrough capacitors?

Hi Hans, nice web page I think.

You bite the bullet and buy the feedthrus. NOTHING else works as well. And, be careful about how you install them, particularly if you're using PCBoard stock for your boxes.

==========
Instead of using ready made tin plate screening boxes ,you could make them
from (double sided) printed circuit board scraps which ,at least in Europe,
can be found on most ham radio fleamarkets . Some time ago I bought 3kgs
=6.6 lbs of the stuff for equiv US $ 8.-
The trick is before soldering the sides together to include a copper wire
at the seams.
4 soldered nuts near the corners allow for a removable cover.

> > away waiting for the new basement!)

(Please call them "Ground Fault Circuit Interrupters". They do NOT
interrupt ground faults, only the circuit...) It's pretty simple, as
you'd expect for such a low price. It's basically a latching relay
that's tripped when an imbalance in current between the output leads
is detected. The way it's arranged, you can trip it by dropping a
resistor from output "hot" back to either ground or to the _input_
neutral. Draw about 10mA or more and it should trip. OR... you will
also find that they will detect and trip on a connection between the
neutral output and either ground or the neutral input, but that
connection must be much lower resistance, of course. You should be
able to use one "as is", armed with that knowledge. Just have your
switch generate a ground fault, and let the interrupter interrupt the
circuit. BUT...beware of nuisance trips from the washing machine!

Cheers,
Tom

The Altoids tin has become the standard enclosure for QRP rigs. The standard Altoids tin is a little small, but the larger size tin is about 190 x 105 mm, a little large perhaps, but not too far off.

However, they do contain a significant number of Altoids so you would need to develop a serious addiction!

Ok this is mildly embarassing, but I am intending to build a tentec as my first radio, so thought I had better start practicing construction. bought a RS soldering station, and a desolder iron. desolder is working great, I am taking apart an old radio. Soldering parts back is proving impossible, the dang work wont heat up!! I remember I need to tin the tip, only it wont tin, just get puffs of smoke and solder balls up, and to even get it to do that I have to run it halfway up the tip, in other words the point of the tip is not getting too hot. Now for what may be the silly part. Is it possible that the 'tip' that came with that iron is not really a tip, but a mounting point for a real tip? Or is the iron defective? It s been years since I learned to solder, and cant remember the details. Will a new tip solve my problem? thank you so much for any help.

Source record: 41706

A typical tip looks like a blunt chisel at the end, usually around 3/16" or so wide. (The width can be more or less depending on the tip's main purpose.) Modern tips are plated to accept solder readily. However, if it's dirty or first being used, you might have to clean it first. What you need to do this is a damp sponge -- a lot of soldering stations include a sponge for this purpose. With the tip hot, firmly wipe the tip on the sponge several times, then immediately try melting some solder on the tip. (Your solder, by the way, should be 63/37 or 60/40 tin/lead, with rosin flux, and nothing else. If you have any other kind of solder, put it away and get the right thing. 63/37 is a bit easier to use than 60/40, since it goes directly from liquid to solid without an intermediate plastic stage.) After a few wipe/tin cycles at most, the solder should freely melt and flow on the tip, wetting it. If it doesn't, you need a new tip.

When you heat a new tip for the first time, melt solder on it to tin it as it comes up to temperature. And later on, re-tin it by wiping on the sponge and melting solder on it whenever it gets cruddy or whenever solder balls up on it instead of flowing and wetting it.

In ye olden tymes, soldering tips were made of copper, and had to be filed to expose fresh copper from time to time. Filing or any other kind of abrasion will ruin a modern tip, so don't take any advice to file or sandpaper it. The one exception might be in an emergency if the tip is shot anyway -- you might be able to get a couple of hours use out of it by filing before tossing it out.

Hi,
It sounds very much like your original tip has the plating worn off it from desoldering parts. Desoldering is hard on any tip, even the expensive Weller temperature-controlled tips can lose their plating in several hours of desoldering components from a board. I do this frequently at work over the years, with the nice Weller WTCP setup, and tips just don't last very long if you're doing a lot of desoldering.
The tip is your comment that solder won't tin the tip anymore on the end, that only farther down the tip will it tin and conduct heat. The plating is most likely gone from the tip's tip :).
I bet a new tip will solve your problem. Buy several if you plan to do much desoldering. Tin the tip with fresh solder before and after every desolder operation--that will help prolong tip life.
If you eventually do a lot of soldering, consider investing in a temperature-controlled iron; it costs more but will last longer in the long run. Weller used to be the top of the line but now other companies offer temperature-controlled solder stations (at lower prices)--but the tips are still relatively expensive, no matter who you buy.

Failing in finding anything commercial that will fill the bill, you could purchase two 102" whips and
cut off the ball at the top of one. Then put one of those after-market ferrules on and tighten. Then screw a collet nut on the 3/8" threads. Then screw the other whip into this. No doubt you will have to guy the thing, but you'll have your 200".

wrote:
>How will you determine the antenna factors?

Granted this is a bit o/t for *amateur*, but it is radio and
homebrew--so here goes!

Since this is for pre-qualification testing (not acceptance testing),
NIST-traceable calibration isn't essential. You can determine the
antenna factors by:

- A/B comparison (at multiple frequencies) to known reference antennas
(half wave dipoles for each calibration frequency)
- Using the same antenna and test source positions
- On the same OATS or in the same semi-anechoic chamber
- Measuring the levels with a calibrated spectrum analyzer or EMI
receiver (which you already have/need for the precompliance tests)
- Adding the dB difference to the (known from theory) antenna factor
of the reference dipole.

This is the same general way commercial EMC antennas are calibrated,
less the certified antenna range and NIST tracability.

If you find a particular emission is close to the limit, use a
half-wave dipole and repeat the measurement. The dipole is arguably
the most repeatable home-made antenna, and is the reference antenna
used by most EMC standards. And if the emission is close to the limit
(within your estimated test accuracy, using the dipole), you'll want
to reduce it (or at least, know HOW to reduce it) before spending
serious money on the formal acceptance tests.

If the part farther up is melting solder properly, then it is most likely that the tip is not properly contacting the heating element. Check to be sure that the tip is screwed in tight. The tips on new irons frequently come loose during shipping (or were never properly tightened during assembly). Even during normal use, I find I have to re-tighten the retaining sleeve on my Wellers a few times a year.

Exactly how to tighten the tip depends on the exact contruction of your unit, but it should be pretty obvious. The advice about the moist foam sponge and initial cleaning and tinning should be observed also.

Thank you both, I think Roy nailed it for me, this thing came 'tipless', it looks nothing like what he described, and I need to go buy one to put on the iron.
As for desoldering, I have a separate gizmo for that, a heater and suction bulb all in one, works like a charm.

<snip>

Suggestion (and no, there's nothing at all embarassing about putting together a TenTec):

Soldering equipment, like any quality tool, is an investment. You get exactly what you pay for. Radio Shack would be far from my first choice for any sort of tool that I'd use the word 'quality' in the same sentence with.

I would, for the sake of both your upcoming kit and your sanity, strongly recommend investing in a good temperature-controlled grounded-tip soldering station from Weller, Edsyn, or Loner. Yes, they'll cost quite a bit more than the basic plug-in-and-go units you'll find at RS (between $125-$250), but they'll last a heck of a lot longer and you gain the versatility of interchangeable tips and far more accurate temperature control than you have now.

If you don't want to buy new, you can poke around on Ebay or at ham swap meets. Don't ever sell yourself short on equipment like this, though.

Good luck.

If, by "homebrew," you're referring to the design, construction,
and modification of electronic equipment pertinent to the ham radio
community, then yes, you've found the right place.

> polyvaricon tuning caps. Is the following a good approach to comparing
> efficiency?

Just a thought:

If you have enough parts to make two of the tuners, you could adjust one up on a real antenna (or equivalent dummy load if you wish), then back to back it with the second tuner terminated in a 50 ohm load and adjust the second tuner for match and measure the power delivered to the 50 ohm load and the power out of the transceiver to calculate an efficiency. If the second tuner was truly a copy of the first, you could share the dB loss equally between the two boxes.

I haven't done this, but I think it would be a suitable test setup that depends on power measurement only at 50 ohms.

I have been thinking of this as a method of measureing the loss of some commercial tuners, but while I have two Might Fine Junk tuners, they aren't the same model, and I am not inclined to buy any more.

I agree with Roy, it's about initially tinning the bit. I have always used Antex irons and find them great, and the tips last for ages (even desoldering!). But always when you use a new tip you have a little trouble.

I recently replaced the tip and until it is tinned it does seem as though the iron isn't hot. This is because the contract between the iron and the subject is only a point, which doesn't provide much heat flow into the subject. Don't touch the tip or you'll find out it is really as hot as it should be even if it doesn't seem like it.

I have also heard about this business of holding solder on the tip while the iron heats up, and find it often helps but not always. I didn't bother with it this time and found that after enduring the first few joints / wipe cycles the tip wetted nicely and now there's no problem.

I have been rebuilding, restroing and repairing Weller WTCP solder station
since 1975 (my first 4 repaired were Collins surplus TCP stations [original
black bakelite] when Weller was in eastern PA).

Bruce is correct, this is an excellent time to find high quality stations
(e.g. Weller, Haako, Edsyn Pace) being given away - largely due to the
bankruptcies in the telcom and "dot.com" industries.
I recommend the TCP series for any new kit builder because of its longevity
in the marketplace, wide availability of parts and ease of service.
In my experience the failure rates are with the SW60 temperature switch and
the EC234 heater (in that order).

Ask questions and purchase used based on very good to excellent cosmetic
condition.

Since it has not been mentioned in this thread , when tinning a new or used soldering tip , I allow the tip to heat up before dipping it into solder cream . This is made by Multicore Solders Ltd ,Hemel Hempstead , Herts -UK
The solder cream contains lead and rosin or modified rosin (as it says on the label)
Followed by a swipe over a moist sponge the tip is clean and ready for use.
Use of the cream is more frequent when unsoldering than when soldering a new board.

To prevent inhalation of the vapour when dipping the tip into the cream a nearby small 12 V computer fan takes care of dispersion. The fan is also used when soldering.
I know ,ideally it should be a full blown extraction system ,which I definitely would have when soldering for a living .
However when soldering infrequently (as a hobby) I consider a dispersion fan as adequate.

Multicore makes a little tin with a sort of hard solder paste for tinning
irons. I think the flux is more aggressive than that in the solder. I find
it very useful.

I strongly agree. When you change to an iron with a choice of both tip size and temperature, you wonder how you ever managed before!

I've been recommending the TCP or similar in my magazine column for some time. The same iron handles everything from PL259s and tin boxes all the way down to SMD. To give an extra boost for very heavy work, use a hot-air paint stripper gun as a pre-heat.

People who have made the change are writing in to say "I wish I'd done it years ago!"

Nobody seems to have asked: Why do we no longer get copper tips for
our soldering irons? When I first started soldering, all were copper
and easy to use/repair as Roy states. Now (except for "gun" tips) all
that I come across seem to require a new tip, and cannot(?) be
repaired after loss of the plating. Did this change somehow benefit
the soldering iron user?

All is not lost. I use a Weller SP-40 pencil for most of my work (tube stuff). The tip is 1/4" solid copper with enough length for filing down for renewal to your hearts content.
It stays on several hours a day and I can get a year out of the tip, soldering and desoldering and have a fresh clean surface with a few swipes of a file.

Don't they all? Every supplier I've ever approached in
Europe has been happy to take my money and ship me whatever
I wanted. I cannot say the same for the U.S.

The first place I looked (Barend Hendriksen) had Eurocard
size boxes for 7 Euros a pop. Dunno about the U.S., but
they certainly export to Canada - I have goodies (and
credit card bills, alas) to prove it.

You betcha! The old copper tips would crud up in a short time (an hour or two as I recall), and would require filing and re-tinning each time it did. And you could only file it so many times before it was too short to use. A secondary effect was that the oxide coating would deteriorate the thermal contact between the tip and iron, so you'd frequently have to tighten the tip. In contrast, a single modern tip will last for years of hobby soldering, with nothing more than an occasional swipe on the sponge to keep it as good as a freshly filed and tinned copper tip. I have absolutely no desire to go back to copper tips.

If you lose the plating often enough for it to be a problem, you're either treating the tips badly (e.g., abrading them, or cooking them for long periods at very high temperature) or you've found some tips of much poorer quality than I've ever seen.

Which iron is it? I have an RS iron that works great. BTW do you mean RS to
mean Radio Shack?

There is plenty of DOS left in Windows, just make a boot disk!

I find that the (plated) tips on my earlier Ungar and current Weller iron
last for years.

Just a couple of points from my own experience:

1. I like using the Antex irons for circuit board work. If you look closely at the design, the tip is a sleeve which goes over the heating element and is then secured by a collet. I have never seen this written in any documentation, but I always assumed that the purpose of this design was to allow you to make fine-tuning adjustments to the temperature by sliding the sleeve further up/down the heating element before securing the position with the collet. Once when the iron seemed to be too cool, I noticed that the collet had worked loose and the sleeve had moved 'up' the heating element. Moving it back down slightly restored the temperature to ideal.

2. Something I noted very recently. I set up a fan system (old PC fan powered by gel lead-acid battery) on the workbench just in front of where I solder. This works fine and blows the flux-fumes away from the work area before I can breathe them. The air flow was aimed directly at the work in progress. Unfortunely I then found that this made soldering very difficult because the solder would not 'flow' as usual. I traced the problem to the reduction in temperature from the fan's air flow. I did not measure the temperature drop but you could feel the difference with your skin and I suspect it was at least a couple of degrees.

3. When you are soldering to boards the amount of heat absorbed/dissipated by the underlying circuit impacts on your ability to heat the joint. For example, I find that large pools of ground planes sometimes make it very difficult to solder a simple part to a pigeon-eye within the ground plane. I assume this is because the heat is lost more easily through larger area of the ground plane.

best regards, ram

If you are an ARRL member you can read the article about how to test antenna tuners on that site. It went over my head, but did draw some conclusions about various configurations of tuners.

Source record: 41737

Been fooling around with a single transistor (2N3904)crystal controlled transciever. The transmitter works fine, but the reciever is not very good. Thinking I could reduce the amount of current drawn, I introduced resistors in the emitter leg. No improvement in signal strength. Even added a transistor for audio, worked ok, but not as good as a direct conversion rig. I just dont think crystal oscillators are cut out for the job of autodyne detection. But, the stability and simplicity sure would be nice. Anyone out there ever tried this? All my circuit amounts to is a basic crystal controlled c.w. transmitter. There has to be some way of getting a decent recieved signal out of this thing. I tried taking the audio out of the emitter and collector leads, but performance is not acceptable, I only hear the strongest ones. Tnx Doug

Why not have a constructive post? Wouldn't it make more sense to start a
thread about construction? Whining about it, is worse than any FS
post. Just a thought.

This raises an interesting question: how do you define "simple"?

On the one hand, the whole transceiver contains just one transistor, so that's got to be simple, hasn't it?

On the other hand, that one device is trying to do several things at once, so it's much more difficult to understand, and much more difficult to optimize the circuit in every respect at the same time. You have so few components and variables to play with, and what's good for one function is probably bad for another.

I've never quite understood the urge to make circuit elements do more than one thing at a time, except perhaps as a kind of "party trick" to show that - far from being simple - you're actually being very clever.

Measured by the time needed to get it working well, it's generally simpler to give each device only one thing to do, and then use as many components as it takes.

Opinions?

I think there may be a few reasons for this "as simple as you can get"
line of thinking.

One is a holdover from the old days, when parts were expensive, big
and added a lot of current to the drain.

Commercial design may have some impact, because there you can spread
development cost over many units, and saving a stage or even capacitor
in each unit may be quite a saving. When people were getting ideas
from commercial equipment, remember the days when the product reviews
in the ham magazines routinely included snippets of the schematic?,
that's what they saw, and undoubtedly there were those who copied

such streamlining.

People starting out make the assumption that as few components as possible is the best choice. They don't know enough yet, so they can't know the tradeoffs of the simple design. All they know is that there will be less soldering (and hence less chance for mistakes), and one or two stages is much easier to follow than a big schematic with lots of stages. They also may need to buy all the parts, rather than scrounge or use junk box parts, so the fewer parts the circuit uses, the less it will cost.

And then there are the people interested in the idea as a goal. How simple can I make this? How few components can I use? The game is to reduce component count, rather than best performance.

One of the neat things about solid-state components is that active component cost, both monetary and size, have pretty much been eliminated. In the old days, you'd rarely see voltage regulation, and virtually only for oscillator stages. Now, voltage regulators are routine, even when it's not necessarily needed, and those small regulators mean you can use them to isolate stages if necessary.

If you can pull dozens of transistors off some scrap circuit board, there really isn't any need to cut out one stage, so you need the other amplifiers in the chain to provide higher gain.

I'm not sure enough people grasp overall design. So they'd rather have a vfo with a dial readout (and the associated calibration and linearization issues), than a digital readout that may add more soldering to the building but which is relatively straightforward and makes the VFO design easier. Or use a single conversion to 455KHz, and the associated issues of tracking, than a conversion to the HF range or even double conversion, where you add stages but do away with image rejection problems.

You look at some computer board, and it's almost shocking to see 3 or 4 crystals (or metal-canned oscillators) on it. "Why didn't they use one single crystal and derive everything from it?" But if they add an "extra" crystal or two, maybe it cuts out other stages or avoids issues of long traces with those clock frequencies. It looks messy, but sometimes the easiest path between two points is not the most direct.

I keep thinking of direct conversion receivers. When that article by Hayward was published in QST in 1968, it was a relatively novel concept. But for a long time, the concept was never particularly developed. The changes were over the type of mixer, rather than dealing with other points. The concept supplanted regen receivers, and a lot of simple superhets, in the magazines for simple receivers. (Simple superhets made a comeback when ladder filters got introduced into the ham vocabulary, at which point it seemed like the faults of the direct conversion receiver became intolerable.) But

it wasn't until the mid- to late- eighties that anything really changed with DC receivers; when the concept of proper loading of the mixer came along. It added complexity to the receivers, but it improved performance. Now, at least in some cases, DC receivers, by adding some complexity, have become fairly high performance.

I look at all the junk I've accumulated over the years, and I realize I'm pretty rich in terms of parts (though, there always seems to be one elusive part always missing). From that standpoint, there really isn't any reason to make something simple in parts count.

I think I have one on paper tape somewhere :^) Seriously,
ask someone over on comp.os.cpm - they should be able to help.

I recall downloading one from a BBS back in my CP/M days,
but don't know where it is now - somewhere in my hundreds
of 5.25" disks. It wasn't very smart, one had to have a
pretty good clue what was data and what was instruction.

Bring 'em to work or a club meeting, put 'em in a dish. Usually you can
get rid of near any kind of food at work that way. One day I'm going to
experiment with stuff like broccoli with prune jelly and peanut butter
to see just how far that goes.

I think it's important to see designs like this. They're great exercise
for the mind.

Different venue, same concept: there was a site I saw that used to show
coding for very small, simple computers used in spacecraft. The 'puters
were chosen because of their record of reliable space use, over more
modern 'puters that were much more powerful but not necessarily sane to
send up on a rocket. Lots of the things that the coders came up with were
useless for the average programmer because of self-modifying code and
other taboo enterprises. But meandering through the code and imagining
the thought process involved was a great way to kick-start the brain.

Lots of tricks that are common today were once "party tricks". Take the
use of the Miller effect in oscillators; in the sixties, it was interesting
but impractical because of manufacturing variances, but by the seventies
it was in use in production TV sets.

Do you have a cp/m machine or a Radio shack 1/3/4 to run it on?

I have options for either of those, but as far as running on x86 hardware, I don't have a native mode dissassembler for the z80. If you really want to go that route, there is still Myz80 that emulates a cp/m machine on an x86 dos machine, then you get access to most of the cp/m software available including the zcpr stuff (excellent tools).

Do you even have the hardware to dump the 2716? Finding an eprom programmer that also reads nowdays is probobly more difficult than finding a z80 disassembler.
thanks, John.

Well after a few months (about 6hours total) I have completed my first project.. The small txcver Pixie II... WHat a wonderfull feeling to complete a rig and have it work. Granted it did not function at first i had a few parts that were not exactly the right values but a little help from some friends and they were replaced.. I Proudly fliped my on swith to the tune of a local bc station... Not really the fault of the radio itself but my choice of antenna designs (a distributive capacitance loop).. After much frustration i added a nice filter from the QRPp-i group worked wonders but so did changing to a 1/4 verticl :)... after frustration on 80 meters..(I guess it was a bad choice for time of year i got the components and crystals to switch to 40... With the new torid and crystals a nice verticle antenna well not nice but simple 33 feet of speaker wire tied to a tennise ball tossed into a tree.. i began to hear my first sound other then am radio. :)... it has been a fun experience and it sure was great to hear some cw... The knowledge i picked up has been invaluable. I can't thank everyone here and on the other lists enough for the help and assistance provided during my quest for fire (so to speak). It has really made my rebirth into the hobby a great one. Thanks for the bandwidth and hope to hear you all soon.

Well Congratulations!!

And yes, 40 is a lot more Pixie-friendly any time of year!

If you are good at your email filters, you may want to subscribe to the QRP mailing list, QRP-L. It's a pretty high volume list, about 100 messages a day, so unless you are a maestro at the email filters it can take a bit of time.

But from time to time there are Pixie nights where others with Pixies and variants get on and chat. It can sometimes be pretty tough making QSO with a Pixie, not only the low power, but the crystal control makes it a little tough, but there are a bunch of them out there. And most of them belong to QRP-L'ers.

I just hunted through last year's archives (I couldn't quickly check this year) and came up with 249 hits on Pixie, so there a few of them out there.

I doubt I can reach Alberta this time of year, but maybe when it gets a little colder and the band lengthens out we can try a 2-way Pixie QSO. Of course, even now, if we pick a day where the A index is low, we might manage it in the wee hours.

..

Can someone tell me if the DIL version of the above synth chip is still
in current production?

An engineer colleague does not wish to work on a PLL design if component
sourcing will become a problem in the near future.

Best pricing so far is $6.50 but that's the 100 off price.

Any other suggested sources for same?

Hi Jacques,
thanks very much for answering...
FT901DM is OK,
I just need schematics (the full manual is not necessary);
Tell me what's the best way for you (e-mail, SASE ecc.)
my e-mail is
iz7ath AT libero.it
Thanks!

Ciao Jacques
grazie mille per la risposta..
l'FT901 e' OK,
mi servono solamente gli schemi elettrici (non
e' necessario l'intero manuale);
dimmi come preferisci fare (e-mail, SASE ecc.)
la mia e-mail e'
iz7ath AT libero.it
Grazie!

Thanks for that link.

I think I scoured most of the web other than the obvious!

I also checked out a couple of other Motorola DIP PLL chips but they all
seem to be nearing the end of their life.

What's going to happen to the small non-SMD manufacturers?

I think you might have to go a little further then alberta :) I live on Vancover Island inVictoria, British Columbia.. And would be more then happy to try a qso. I am on most sundaynights but i am planning on switching to saturdays from 7:30 until about 10. Operating on 7.122 and then 7.040. Last night was really active i heard quite a few sigs some i might actually have been able to copy except for my slow speed :(... I'm trying to figure out how to set up some sort of rit so that i can be a little bit more flexable.. i know there are a few mods out there for the pixie so i am going to work one out shortly hopefully... that and more practice with the code generator as my proficiency is not as good as it could be.

Will definitely post about my first qso today i am working on moving my antenna to a more vertical location... I have a tree in the front that should provide a high enough hold for it... I'm sure it will work better then the current setup about 15 feet up and 15 feet horizontal.. Will have to see. Definitely keep you posted.

No new designs, either homebrew or commercial, should be using those old MC-series parts. Look into the Analog Devices (http://www.analog.com/technology/RFComms/rfif/phase.html) and National Semiconductor (http://www.national.com/appinfo/wireless/) lines instead -- they are way cool.

Because these chips have only 16 pins, they can be (very carefully!) hand-soldered if you can't find a prototyping adapter for them.

Congrats, Jason. The Pixie II is a minimalist transceiver but is a fun radio
for almost no money invested. Several years ago the gang on the QRP-L got into the Pixie's pretty heavy. There are seemingly endless websites
and discussions on this little $9.95 transceiver.

If you would like to read the QRP-L and not have to put up with a massive amount of emails, you can read the QRP-L on this URL
http://listserv.lehigh.edu/lists/Archives/qrp-l/date.html

This one is by date but you can select date, author, or subject. To be able to post to the reflector then you will have to subscribe to the reflector. This web version is updated about 10 minutes after each hour.

Message-ID: <3d7b1bd3.6830477@news.dodo.com.au>
Source record: 41677

Hello again Scroungers

Just letting you know that the article on Easy AO40 Rx has been
updated with more detailed pictures.

It can be found on the front page of Central Goldfields Club at:

http://www.cgfar.com

For those who wanted PDF, I'm sorry.... I just couldn't
package the thing properly, so I'll ask the Webmaster to make
the original raw pix of the circuit boards available for download.
Next time, I'll do better.

I'm fiddling with the Pacific Monolithics (Hills) downconverters
at the moment. I found some interesting related stuff on the
US patent server (see article).....

When I learn how to re-tune them, I'll post it on our website.

Keep fiddling !..... 73 de Chris

2116. FS: Old Radio Related Books (1937-1977)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-08 14:52:49 UTC
From: oldbooks78@aol.com
Message-ID: <20020908105249.20741.00002638@mb-mo.aol.com>
Source record: 41679

I currently have for sale the following old radio-related books. Postage is $2 for the first book and $1 for each additional item (Media Mail within the US, at cost elsewhere). The books are:

ARRL "The ARRL Antenna Book, 13th Edition" American Radio Relay League, 1977. The 336 page softbound book is in about very good condition. Clean with no page tears or pen marks. The covers show a bit of wear from previous use, but not bad at all.A comprehensive treatment of radio antennas. Available for $7.

Jordan, Edward C.; Paul H. Nelson; William Carl Osterbrook; Fred H. Pumphrey; Lynne C. Smeby; and W.L. Everitt (editor) "Fundamentals of Radio" Prentice-Hall, 1944. The 400 page hardbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Gray cloth covers with some minor spotting on the front cover, otherwise nice. A nice early radio related text. Available for $10.

Siegel, Hy "All About CB Two-Way Radio" Radio Shack, 1976 Soft Cover. The 112 page softbound book is in very good condition, clean with no page tears or pen marks. Nicely illustrated. Available for $5.

US War Department "Technical Manual - Radio Fundamentals, TM 11-455" U.S. GPO, 1941. The 140 page softbound book is in fine condition, fresh and clean inside and out except for a previous owners name on the front cover. A nice WWII vintage radio manual. Available for $10.

Federal Telephone and Radio Corporation "Reference Data for Radio Engineers, Second Edition" Federal Telephone and Radio Corporation, 1947. The 322 page hardbound book is in good+ condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover. "The present edition has been greatly enlarged and a subject index included. Chapters on transformers and room acoutics have been added. The material on radio propagatiion and radio noise has been revised. The data on cathode-ray tubes have been considerably expanded." Available for $8.

Everitt, William Littell "Communication Engineering" McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the science of the radio. Available for $9.

Measurements Development Laboratory of the Sperry Gyroscope Company "Microwave Transmission Design Data" Sperry Gyroscope Company, 1944. Publication No. 23-80. The 215 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Originally issued during WWII as a "confidential" document. Chapter topics include General formulae for concentric lines; Attenuation in concentric lines; Reflections and impedance

matching; General formulae for wave guides; Attenuation in wave guides; Reflections and impedance matching in wave guides; Wave guide tees and bends; Wave guides filled with dielectric material; Dielectric material: Cavity resonators; and Measurement techniques. A neat early book on ultra-high frequency radio waves. Available for $10.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

It's a great little transceiver and very fun to use. I made one with a ceramic oscillator so I could pull it all over the 80 m band and have actually worked 15 different DXCC entities with it from Oslo, Norway. I realize that I have countries closer to me than most North America readers of this group, but anyway it is amazing how much you can do with it. I did most of my countries in a contest this spring. I don't remember which one, but suddenly the 80 m was full of exotic stations! See http://www.qsl.net/la3za/QRPp.html It takes some getting used to to put the rx frequency on the right sideband and at the correct offset, and it is always much better to reply to a CQ rather than to try one yourself.

73 and good luck!

Sverre LA3ZA

2118. 432MHz xvtr with tube EC8020 - pse help

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-08 20:13:59 UTC
From: Richard J <nospam@mah.se>
Message-ID: <algb1vrih1@news.lth.se>
Source record: 41681

Hi group -

have "inherited" an old 144>432 MHz transverter from (probably) the early-mid 70:s. It was built by someone in Sweden after some design that was published at the time, in SM, DL or someplace else in EU.

It is modular (LO/Mixer module, RX/TX module in small alu boxes abt 2x10x19cm, looks like a VHF Communications or similar design and has a separate module built with epoxy/fiberglass PCB containing a tube-equipped low-power PA, using a single EC8020. Havent opened the boxes yet, but I bet it's an early stripline design inside all modules.

It drifts like hell, is reasonably sensitive on RX, is vy low-power, but WORKS and I'd like to dust it off and use it for fun and to show the youngsters that things can be simple and still do the job.

Now, who remembers such a device these days? Any bells ringing, especially with you EU hams?
I'd be happy to know the following:

a) there has to be an article or a description for this thing somewhere.
b) the EC8020 tube is an old Telefunken with diamond...I'd need a replacement or a substitute - either direct sub or sub after modification of cct - in case this one fails or gets weak. Ideas?
c) I cud use some application data for the tube when used for VHF/UHF, failing all else. I'd like to know max input, max anode dissipation plus max anode voltage etc etc..

I know you guys, you have the answers to this one :-) If necessary, I'll mail you some digital pics of this dusty beast and its innards.

TIA for your time and replies /cheers /Rick, SM7SCJ

==========
The EC8020 is indeed a Telefunken triode used in grounded grid config for
VHF/UHF amplifiers

P(anode) = 8 W

Specsheet : http://frank.pocnet.net/sheets/117/e/EC8020.pdf

This is a spec sheet which can be found through a very elaborate Valve site
showing more than 15000 valves :
http://home.wxs.nl/~frank.philipse/frank/frank.html

Here you also can find other European and US equivalents

Yea Jason! Dude! It's always cool to glom together a bunch of parts
and have it work... and the feeling never goes away, not even when there are
a lot of other people in the chain -

Like, have you seen the latest Sprint PCS ads for PCS Vision? I archicted
one of the most innovative features in the Java-equipped phones (long story,
just go with the punchline) and it gives me the same kind of kick to seem the
new phones on TV that I helped create.

The feeling, be it a box of components or a new way to deliver cool
services to people, it's always the same! This isn't meant as a brag,
I was a 14-year old with a homebrew transmitter once, and the feeling
is much the same 25+ years later on a much larger scale... it never
goes away.

Great job!

From: Joe McElvenney <ximac@btinternet.com>
Message-ID: <VA.000001d1.003908ae@btinternet.com>
Source record: 41686

Hi,

I've just acquired the subject unit and would like to ask a couple of questions from any fellow owners out there before I attempt surgery. I'm using this 141T with a 8552B and an 8553B/8555A combo. It is a long time since I've used a 'boat-anchor' SA having had more experience with the later HP85nn series.

Firstly, when setup according to the manual, does the bottom of the noise floor normally move upwards? If so how much at the minimum attenuator setting. Mine seems to have a DC shift of up to two divisions although the signal peak tracks the graticule OK. I also visually lose the signal at about -100dBm which would still be audible on the bands.

Switching to storage doesn't seem to show any negative going noise peaks that might be charging the detector time constants and so moving it up. Of course the 'vertical thickness' of the noise increases just as one would expect when the 'Log Ref Level' is reduced.

Secondly, I get a good bright display but am concerned that the variable persistence display is too bright when I reduce its setting and the screen floods completely (blooming though is not a problem). I know that this is a subjective question, but how bright is normal? Reducing persistence is achieved by varying the flood gun current so one would expect an increase in brightness but this seems over the top.

TIA - 73 de Joe, G3LLV

I have the Following Transistor radios; G,E, P745, 3-G.E. P807
series, Crown TR610,Zenith Royal 20.
I am asking $120.00 Plus shipping for all 6.
The radios are complete including correct knobs.
I have a lot so if you need anything let me know.
Regards
Louis

Obviously, they're eventually going to have to get out of the non-SMD business. An SO-16 isn't all that tough to hand solder. Even the TSSOP's are manageable if you have a good solder mask on the board. And just think of all the drill bits you'll save!

This is one of the biggest problems with the Pixie. If the other station carefully zero beats you (as he should) you won't hear him! The most common workaround is to put a switched capacitor across the crystal. You now have to manually switch between transmit and receive, but at least you can hear the other station.

On what band and with what plugin? The higher microwave bands with the 8555A will probably exhibit some baseline lift, to compensate for increased conversion loss due to mixer loss and a weaker harmonic signal from the YIG.

-100 dBm at what center frequency and resolution bandwidth? That might be appropriate at high RBWs. Remember that your SSB receiver runs at an effective "resolution bandwidth" of 2 or 3 kHz, while the 8552B maxes out at 1 MHz. Neglecting receiver-generated noise, the noise floor in a spectrum analyzer at 1 MHz would normally be 25 dB higher than the noise floor in a receiver with a 3 kHz filter (=10*log(1 MHz/3 kHz)).

My guess is that you're in good shape if the analyzer reads the correct signal amplitude (+/- 2 or 3 dB) at several points across the band.

I don't remember how the 141T display works in particular, but it's probably OK. Just don't leave a bright trace on the screen for longer than necessary. Fortunately, spare tubes for the 141T are both common and inexpensive...

And, the noise figure for the SSB receiver is probably well under 10
dB, whilst the 8552B is likely 20 dB or more.

I agree that we will all have to get used to SM
I think the difficulty has been overstated. With a standard magnifying lamp costing about $100 and some fine instruments it is easy to solder these devices if you have a good quality PCB. Admittedly they are more difficult to breadboard. I would think few if any manufacturers are developing new components in a DIP package

From: Leon Heller <leon_heller@hotmail.com>
Message-ID: <alkj9s$i5j$1@venus.btinternet.com>
Source record: 41605

I've set up a web page describing a simple four-pole crystal ladder filter design procedure, and a link to G3PTO's web page with a circuit for matching the crystals. Included is PCB artwork for the filter and the crystal tester.

The URL is: http://www.geocities.com/leon_heller/ladder.html

The PCBs were designed to be made easily at home. Pics of my home-made prototypes are on the web site.

I''ve had a quotation for making a small batch of the PCBs. Price will be $8 each, including air mail postage. I'll only go ahead if I there is sufficient interest. Several QRP-L subscribers have already said that they want them.

This is quite an elegant design, but may require careful adjustment of the potentiometer to assure correct video separation. Also the mixing levels may be all over the place.

You may want to take a look at the 'retro games console' project on the AVRFreaks website (www.avrfreaks.net). It has schematics and source code included. You could easily modify this project to produce video overlay (using a LM1881 sync separator for instance).

I saw a good idea for breadboarding smds, you bought a pack of little
pcbs made up for different types of smd and the lines from the pins
were expanded out to dip size, these little pcbs were sticky backed
and placed then on a blank piece of pcb as a ground plane then
you could hard wire them up, admitted you still had to solder the
device to the little pcb but it did go some way to making breadboard
smd easier.

My Pyramid 12A supply blew out the other day. I just got into it to fix it.

It's not awful; they use a separate power supply for the regulator
and driver transistor than they use for output. Transformer looks beefy
enough, wound with about #16 wire, separate winding for the low-current
regulator supply.

But when I found the shorted diode and looked it up... it's a 6A diode.
This is one of two diodes in a full-wave center-tap configuration, and
it's obviously not in parallel with anything. (PX6A02 for anyone who
wants to check.)

"FULLY REGULATED LOW RIPPLE", I'll bet. 2 x 4700 uF in parallel for a
12A supply doesn't seem sufficient to my mind.

All I can say is that I'm glad I never tried to pull more than a couple
of amps through this thing.

=========
Indeed above components seem to be rather marginal.
Perhaps it's a bit overdone but for the above power diodes I would suggest
stud mounted 40 A diodes .
Had a look in my junkbox and found a few 1N6097 made by TRW and some 40HF40
made by IR (International Rectifier)

In 1999 on this NG Roy , W7EL gave some useful advice on sizing ripple
reducing capacitors.
I kept the info in a paper file . In it he gave an example for a 1.5 Ampere
PSU resulting in a 12,500 microFarad capacitor
In another design from a mag. for a 20 Amperes PSU the said capacitor is
120,000 microFarad.
So for your 12 Amperes PSU 100,000 microFarad would seem fine. Upon
switch-on the resulting inrush current can be readily handled by the 40 Amp
diodes.

There is a new Ham Radio Portal online at

http://www.hamradio-portal.com

This Portal contains news, Information and

special topics like Echolink software and many more.

It has a Weblink and download database.

A new Webboard to discuss topics is also there.

You can also submit news and topics what

comes available on the top of the page!

It should not to be in compete with other Portals.

Just a new one with a new look and nice features.

We hope to see you there!

Andre

Clifton:

I am guessing that the 12A rating on the supply is not intended for continuous operation. Perhaps it is 12 amps intermittent and 6 or 8 amps continuous. Keep in mind that with a center tapped secondary, each diode only conducts 1/2 the time (on alternate halves of the AC cycle), so they do share the load as if they were in parallel, but a 6 amp rating on the diodes seems too optimistic. I would suggest a 12 amp diode, maybe 15 amps, since then they will be running at about half of their rating.

The amount of filter capacitance you need is not simply a function of the current drawn from the supply. It also depends on the rectified, unregulated DC voltage on the capacitor(s). If the unregulated DC is only 15 or 16 volts, then you need more capacitance than you would if the unreg DC was 18 or 20 volts (or higher). You didn't state what that voltage was.

The capacitor(s) don't have to remove all ripple...they only need to hold the voltage up in between the 120 Hz pulses from the diodes so the regulator can do its job. If you have an oscilloscope you can put it across the capacitors and measure the minimum value of the varying DC when the supply is furnishing its rated current load...as long as the voltage across the caps stays above the minimum needed by the regulator, you have enough capacitance. You can have lots of ripple on the caps as long as the minimum value of voltage allows the regulator to work correctly.

If you don't have a scope, you can get a fair idea by measuring the value of DC voltage across the caps when the supply is putting out its rated current. If the voltage across the cap(s) is at least 3 or 4 volts higher than the regulated output voltage, under full load, then you probably have enough capacitance. If not, then more capacitance is needed.

Hi Bill,

Quadfilar means that four (4) wires are wound together, in parallel.
Your drawing needs color for each winding to clearly answer your
question, also, it needs phase dots on the schematic to correlate
correct connections. 1 & 3 appear to be backwards, as do 5 & 7; but
without the individual windings visible, or phase information, it is
difficult to say.

What you have in your mind, and what you have posted may well work,
but without these details, I for one, could not respond in the
affirmative. Reasons for my saying 1 & 3 appear to be backwards is
due to all windings starting at the same end (presumably 1,4,5,8)
would not find 1 & 3 in proximity with 2 & 4 connected unless there is
a phase inversion not shown. [Same goes for 5,7 and 6,8.]

Hi Richard,

Thanks for the quick response. Perhaps I posted this a bit too soon and maybe should have contacted the designer of the circuit first, which I have now done. Thanks for your input and sorry for the inconvenience.

Bill

Hi Bill,

No inconvenience at all, you came more prepared than most who have
grand designs of naming an antenna after themselves. You might also
include what you are going to use this for - it could be significant
to consider in light of that application. And you never know, someone
else might chime right in with a less equivocal (and still correct)
answer than mine.

I had 2 Astrons 20 A PS go out on me in a week... Both blew out the Bridge rectifiers in a brown out. Nothing else, including a computer (all on at the time) was harmed. Just the two Astrons. Weird! But then that week was weird, 2 brown outs. We usually get blackouts or nothing at all.

Well, wait a minute. In a linear-regulated supply, there's no point in using larger filter capacitors than necessary to keep the ripple troughs higher than the regulator's dropout voltage, with perhaps a few volts of safety margin. If the regulator's input voltage is 25V on a 12V supply, for instance, then 10,000 microfarads is probably plenty. Such a regulator would need to dissipate a lot of heat with a 6A load, of course, but the supply designer may have seen that as a reasonable tradeoff.

Generally, regulated supplies don't need as much input filtering as non-regulated ones.

That's absolutely correct. The information I posted allows you to
calculate the amount of capacitance you need for a given amount of
ripple at a given current. But it doesn't address the amount of ripple
you can tolerate -- that's up to you to decide. And as jm says, there
are tradeoffs involved. The 12,500 uF value was an example calculation
for a specific amount of ripple, which might not be anything like the
amount you can tolerate in a given application. First decide how much
ripple you can tolerate and how much current you'll be drawing. Then
calculate the amount of capacitance it'll take to get that amount of ripple.

Everything on the front panel suggests they mean 12A continuous. There's
no mention of a smaller current.

You betcha. I never underrate when replacing, even if the designer did.

I didn't measure it. They're 25V caps, and I was going to make a guess
based on that, but considering they advertise 12A through 6A diodes... :)

> The capacitor(s) don't have to remove all ripple...they only need to hold

Right. I just suspect 12A would run the charge down on 9400 uF of caps
pretty fast. (Headache precludes any calculations at this time.)

> If you don't have a scope, you can get a fair idea by measuring the value of

The real fun is that extra regulator supply. If the main voltage drops
low enough, it could forward bias the base-collector junction on the
pass transistors. In any event, the smaller supply could end up with a
10A load on it when the main supply drops low enough. That could let

all the smoke out of the teeny rectifiers in the small supply.

For what I've used it for, it hasn't been bad. I don't think I've ever drawn more than about 5A out of it. (I said "a couple of amps", but I remembered later having powered an old 2M Sears-su from it for a few minutes.) I guess if you buy twice as much Pyramid power supply as you need, you're okay.

>12A supply doesn't seem sufficient to my mind.

The 12 A will discharge the 9.4 mF capacitance at 1300 V/s or 1,3
V/ms. The problem is how to determine for how long the capacitors
needs to supply the load without help from the rectifiers.

The theoretical worst case for 60 Hz full wave rectification would be
8.3 ms, thus, the voltage drop would be 11 V. Assuming 12 V regulated
output and 2 volt regulator voltage drop, the voltage at the end of
the discharge period would have to be 14 V and the initial voltage at
the beginning of the discharge period would have to be 25 V. This is
also the AC peak voltage (omitting any rectifier voltage drop and
copper losses), thus, the secondary voltage would have to be 18 Vrms.

Thus, I would not consider that the claim for 12 A output would be out
in the blue, however, the average capacitor voltage would be 19 V and
with a 12 V output, the voltage drop would be 7 V and with 12 A, the
power dissipation would be 84 W, requiring a few transistors with
realistic heat sinks.

Fortunately, the situation is not quite that bad, since the discharge
is less than the half cycle time, since the rectifiers are supplying
the load for a short time (less than a millisecond) after the peak
(until the AC waveform drops faster than the voltage drop rate in the
discharging capacitor). The next AC half cycle will reach considerable
levels quite quickly (e.g. 50 % of the peak value at 30 degrees from
the start of the half cycle).

Calculating the actual conduction angles can be best done with a
spreadsheet by trying out various values. The rectifier must start to
conduct before the capacitor drops below the drop-out voltage (in this
case 14 V). The start-of-conduction angle depends on the AC peak
voltage, so trying out various peak values will give the time when the
rectifier starts to conduct.

The rectifier stops to conduct, when the AC waveform drops faster than
the capacitor discharge rate, thus the angle can be calculated when
the rectifier stops to conduct and thus the AC peak voltage can be
calculated.

In practice, the rectifier voltage drop must be included and the
voltage losses in copper must be calculated. It should be noted that
the peak current is many times larger than the DC load current (and

hence voltage drop) and the peak current increases when the conduction angle is reduced, making it harder to determine, when the rectifiers stop to conduct. With a spreadsheet is easy to try to find a solution that does not contain any internal conflicts.

I don't know about the one you are talking about, but the pyramid that I use stated clearly on the box what the constant and peak ratings were. Pyramid like everyone else puts the peak rating as the number on the box. Mine is quite comfortable running an Icom 706mkIIg, htx242, 12 volt fan, charging the 12 volt battery pack for my handheld, powered speakers etc. all at once, though only one transmitter keyed at a time. Except for the time it was turned off to move to the new apt it has been on 24/7 since I got it over a year and half ago.
thanks, John.

yes, it will work,
but dynanic performance will be very poor!
why don't you try a H-mode mixer using a
Fst3125 or 74HC4066?
take a look here
http://www.warc.org.uk/cdg2000%20files/frontend/frontend.htm
ciao!

From: Philip de Cadenet <Philstheboss@thebbc.fslife.co.uk>
Message-ID: <aK61jr$olvf9Ewmr@fslife.co.uk>
Source record: 41639

Thanks to everyone here that reflected on both the 145170 DIP package
and SMD status for the home-brewer.

While I have found a couple of outlets who specialise in discontinued
semiconductors with stock of the above at $4.50 I have looked at another
inexpensive VHF PLL layout using the following:

74HC4060

74HC4046

74F160

74HC4059

Cost under $10 US for the complete synth.

Beat that:-)

Mine didn't come in a box; it was new and unpacked at a hamfest, bought
from a dealer I knew. Can't find a picture on the web; it doesn't look
like the PS-12KX model, it's a PS-12 (no suffixes). The PS-12KX says on
its front panel, "10 AMP CONSTANT / 12 AMP SURGE". Mine says:

PYRAMID
PHASE III
by tenna
PRECISION REGULATED
DC POWER SUPPLY
* OUTPUT: 13.8 V. DC 12AMP. WITH SURGE PRO-
TECTION*FULLY REGULATED LOW RIPPLE
* ELECTRONIC OVERLOAD PROTECTION WITH
INSTANT AUTOMATIC RESET
* INPUT: 117V. AC 60 HZ * FUSE PROTECTED
MODEL NO. PS-12 13.8V 12AMP

The only other markings are next to the fuse, "USE 4AMP", and of course
"ON"/"OFF" by the on-off switch.

> V/ms. The problem is how to determine for how long the capacitors
> needs to supply the load without help from the rectifiers.

The current in the load is the applied voltage divided by the load resistance. Just past the peak of rectifier output, at 90 degrees phase, the capacitor becomes the power source because its voltage, not the lower rectifier output, is the applied voltage. So basically it's going to power the load from that time until the rectifier output rises to the amount needed to power the load.

The first spec sheet I find for the 2N3055 says the Vcesat at 10A is EIGHT VOLTS. Drop it in half because there are two in parallel and call it 4V. (Yeah, I know, but the whole thing is silly anyway; to get that we need 6.6A of base drive, which the smaller regulator power supply probably can't even get near with its one- or two-amp diodes.) The transistors are okay, because both the 12A and the 96W are within spec.

So from the 90-degree point to the next time the diode is putting out 17.8 volts, the capacitors are supplying all the power.

Let's assume 25.0V peak out of each diode, a maximum for 25V caps. The diode they use is specified at 1V drop at its rated 6A; let's be silly and keep that at 1.0V for the 12A output because it makes the PS look better than it really is.

The caps will drop from 25.0V to 17.8V in 5.5 milliseconds at 1.3V/ms. 4.16 ms of that time is spent with the transformer voltage going to zero, the rest on the rise again.

The transformer voltage will be at 18.8V (17.8V plus 1.0V) again in arcsin(18.8/26.0) degrees, or 46.31 degrees. (At that point the diode output will be 18.8V - 1.0V, or the 17.8V we need.) At 60 Hz it's 46.29 us per degree, so 2.14 ms after transformer zero, or 6.31 ms after the previous peak. But by that point, the caps had discharged to 16.8 volts, too low to sustain full output. With the 4V drop of the two pass transistors we've lost regulation and rippled by 1V peak.

At the point where the cap is no longer at or above 17.8V, we're into the next half-cycle by (5.5 - 4.1666) or 1.333 ms. At 46.29 us per degree that means we're 28.8 degrees into it. At 26V peak, we have

12.5V out of the transformer, not enough to even conduct yet because the diode cathode has just under 17.8V on it. So our ripple pulse time is roughly 17.5 degrees, or just under a millisecond for best-case assumptions.

To get this *good*, we had to make a lot of unreasonable assumptions, such as the small supply with the definitely-not-six-amp diodes supplying 6.6 amps; the big-supply 6A diodes dropping as little at 12A as at 6A; the Vcesat of the pass transistors having the 10A value at 12A, and paralleling pass transistors halving the Vcesat; and so on.

My conclusion: the design is marginal and expects more of its components than they can deliver. The 6A diodes will survive because their duty cycle at 12A is 25% each (NOT what my wild-a** guesses told me), but 12A or better diodes should have been used for lower barrier drop. The supply itself cannot deliver 12A with full regulation for more than 5.5 milliseconds, probably less with real-world values.

<http://www.halfin.com/semipp/2N3055.pdf> for the spec sheet I used.

Your right, you should have at least 2.000uF per amp in a well regulated
power supply.

It beats me why a lot of Radio Amateurs pay thousands for their transceivers
and then go and spend
as little as possible on their power supply.
To my mind the power supply should be the most respected piece of equipment
in your shack
(OK, earthing should be joint number one).
If your power supply develops a short circuit on the pass transistors
there's a good chance you will end up with around 25-30 Volts on your output
terminals and guess what that does for your shiny new 2.000 plus rig...!!
When it comes to power supplies, get the best FULLY protected unit you can
find. Better still Build
Your Own.....Cheers to all, Ken, G4KIR.

Source record: 41549

Jason - they work, and they work well. Probably 75% or more of the QRP transceivers use a 602, or it's equivalent, the 612. You can interchange the SA/NE 602/612. Check the net for manuals containing schematics of practically any QRP rig. With rare exceptions, the receiver will use a 602 or two (you can use them as product detectors as well.) A little history lesson, Phillips bought the rights to the chip and changed the designation from NE to SA. The difference between 602 and 612 is one of testing, the specs are identical. So an SA602 is a perfectly good replacement for an NE612. Generally 612's are a little cheaper, but the part is tough enough to get that nobody uses the price as a criterion. radioshack.com used to sell the 602 for 2.95, the 612 for 2.25. They don't sell any parts that aren't in the stores anymore. It is getting hard to get the DIP parts in quantity, but the SMT part is still being used in cell phones, so it's pretty available.

One of the nice things about the 602 is that it is sensitive enough that no RF amplification is needed in the lower HF. For 40 meters, just poke an antenna into the input, and add a 40 meter crystal, and audio will come out. A 386 audio amp completes a very minimal receiver.

As Talino points out, however, the 602 is susceptible to significant intermod. This is more of a problem on 40 than on the other bands, and more of a problem in contests. A strong nearby signal will cause all sorts of grief, so a tight front end can help a lot. For 40 that front end doesn't need any amplification so it can be pretty simple business. This problem is extremely serious in Europe, however, making the 602 practically useless there, especially on 40, thus Talino's comment.

The 602 is noticeably poorer than a passive mixer receiver, but the passive mixer adds a bunch of complexity, and it rarely is an issue on this side of the pond. The Elecraft K1 has the best implementation of a 602 receiver that I've come across, and the schematic is available on their web site for you to study. Even though this is the top-of-the-line for a 602, and far better than the run of the mill 602 rigs, it is noticeably poorer than the NC-20 or K2. It is, however, approximately equivalent to the $1000 class Yaecomwood's. So a well designed 602 can be pretty decent.

If you can dig up the schematics, also look at the Small Wonder Labs SW+ series and the NorCal SMK-1 for application examples.

I'm selling my Tek 494P spectrum analyzer after a recent upgrade. This rig has just about every conceivable manual and accessory and comes with a 3-day buyer inspection period. It's the cleanest one I've seen.

This particular unit has the mixers needed for coverage between 10 kHz and 40 GHz, and includes a built-in signal counter with 1E-9/day timebase. Useful for IMD measurement, harmonic and spur evaluation, FCC pre-submission testing, synthesizer noise characterization, and too many other applications to list.

No reserve, starting bid $1.00.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday September 15th 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and

Thanks verry much you have answered all of my followup questions :)... I
was planning on using a PTO For my oscilator...they noted a 500k range on
the one i was looking at putting togeather.. and well i wanted to move to a
mixer that would provide a little better signal to the 386 then the
transiter detector used in the pixie.. I'm asuming the 602 has some gain so
that should work out well.. i have the design for the audio section already
i picked it out of one of the pixie mods... so looks like i may get my own
little recver up and running.. as far as making a transmitter well i'm sure
i can figure something out to get a little more power out then 250 mw but
thats another project...

>The current in the load is the applied voltage divided by the load resistance.

In a regulated series pass power supply, the discharge current is
defined by the _regulated_ output voltage divided by the load
resistance, thus, the load current will remain constant throughout the
whole cycle. For a shunt regulated power supply, the capacitor
discharge current varies with the capacitor voltage.

>Just past the peak of rectifier output, at 90 degrees phase, the capacitor
>becomes the power source because its voltage, not the lower rectifier
>output, is the applied voltage.

Not quite. Assume for a moment that the rectifier stops to conduct at
90 degrees and that the peak voltage is 25 V. Looking at the situation
0.5 ms later (at 100.8 degrees), the capacitor voltage would drop to
24.35 V and the rectified AC to 24.56 V, so the rectifier would
conduct again ! In reality, it conducts a while after the peak.

In a practical situation with some resistance in the primary and
secondary and the rectifier current dropping at and after the mains
voltage peak, the voltage drop in the secondary is reduced and the
actual capacitor peak voltage is reached sometimes _after_ 90 degrees.

I am using the Motorola data sheet for the 2N3055 and I assume that
the figures show typical values. I also assume from your description
that a separate higher voltage power supply is supplying the base
drive.

In the Motorola graph for 8 A collector current and with 0.5 A base current, the Vce is 1.4 V and driving it to saturation 1.5 A is required, with Vce at 0.55 V. Interpolating for 6 A, 0.3 A would give 1.0 V and 1 A 0.45 V. Thus, 14 V minimum capacitor voltage should be sufficient, assuming 12 V regulated output (and not 13.8 V, at which level most mobile transceivers give their rated output). Also the 1 A base driver supply should be sufficient.

>The
>transistors are okay, because both the 12A and the 96W are within spec.

The maximum junction temperature is 200 C and the junction to case resistance is 0.657 W/C or 1.5 C/W and since there are two transistors 0.75 C/W. At 96 W, the junction temperature is 72 C above the case temperature. Setting the junction temperature to 200 C and assuming 20 C ambient temperature, the transistor case temperature is 128 C and the heatsink thermal resistance must be 1.1 C/W or below, which makes the heatsink quite large.

Any electric isolation between the transistors and heatsink will have its own thermal resistance, thus the thermal resistance of the heatsink must be reduced by that amount. Dropping the maximum junction temperature to 180 C for better reliability and allowing 40 C ambient would make a fan almost mandatory.

A regulated power supply can be implemented either with a large capacitance, low RMS voltage and low power dissipation or with low capacitance, high RMS voltage and high power dissipation.

The low capacitance high voltage version has several disadvantages.

* The power dissipated in the series pass transistors must also be delivered through the transformer and rectifier, which makes them bigger and more costly.

* Larger heatsinks and possibly even a fan is required to transfer that extra power into the ambient, which also will increase the cost, if continuous duty is required.

* At no load or minimal load, the capacitor voltage can be quite high, thus, a higher voltage capacitor may be required, increasing the cost.

* A high capacitor voltage is not very nice if there is a series pass transistor short, thus a crowbar would be nice to have.

While you can save by using smaller capacitors, but the additional costs in various other places makes this approach not so attractive for continuous duty cycle. However, transformers and large heat sinks have a quite a large thermal time constant, thus in low duty cycle operation, there is not so much need overrate the transformer and heatsinks to compensate for the extra power dissipated in the series pass transistors.

But is ham radio a low duty operation, when some hams talks several minutes without listening to other operators :-).

Looks good, there was an SB filter thread on the Yahoo group,
amateur-repairs. I don't have any filter info on my round n green
webpage, http://www.kiyoinc.com/heathstuff.html There are other
musings about SB's that you might find interesting.

This page is very preliminary so website critics, go easy.

I'm interested in an AM filter too. I've bid on several SB-313's and
they are going for WAY more than I'm willing to pay. I guess people
are buying them for the AM capability.

There are two different AM filters, 3.75 kHz and 5.0 kHz. I'd consider
building one even wider, 6.0 kHz or even 8.0 kHz, for international
broadcast.

Remember that here "the load" is the regulator circuitry delivering 12A.
So capacitor current clearly varies, from charging when the transformer
is at peak output to heavy discharge when the transformer output is less
than the capacitor voltage.

Mainly, I was only justifying the idea that the higher voltage prevails
and delivers current, while the lower voltage idles; i.e. the transformer
stops being the current source after (a bit past) 90 degrees.

Not sure about the voltage, haven't measured yet. It's off a separate transformer winding with a full-wave bridge rectifier. Considering, it doesn't need to be higher in voltage as long as it can put 13.8V plus the Vbe of the 2N3055's on the bases of the 2N3055's, yes?

Since we need a common ground for this, I searched out the ST data sheet at <http://us.st.com/stonline/books/pdf/docs/4079.pdf>; the unit uses two of these. They, too, show a 10A Vcesat of 3V at 3.3A base drive. I'm sure if you dropped the base current the Vce would go up; I'm also pretty sure the Vcesat will be higher at 12A than at 10A.

Don'tcha just love spec sheets? Enough "fine print" to please any lawyer. :)

Right, but in fact it's not very large at all; another reason not to think this unit can deliver 12A continuously, as it suggests. Well, at least they didn't mount them to the case and expect the sheet metal to do the job.

I made dozens of these
Rocks:
3393.7 kHz
3396.8 kHz
Effective series resistance: 25 ohms maximum
Load capacitance: 35.4 pF
Frequency tolerance: + / - 50 Hz

Values of C1 and C2= .5 PF (yes point 5) and gimmicks dont work to well
I never understood this, and had sharper cleaner performance plots omitting
C-1 and C2.
(C-1 and C2 ARE in the original Heath blueprints)
Value of C3=56 PF
Winding details for L1: (use a pull from bad 2.1 KC SSB filter, they have 2
of these cans).
I have used 2- fixed 2uH chokes in the past and a mini variable from MOUSER
for C-3 in the past

a
> mixer that would provide a little better signal to the 386 then the
> transiter detector used in the pixie.. I'm asuming the 602 has some gain
so

The 602 has about 17 db of gain at 45 MHz. They don't specify how much it has a lower frequencies, but in practice it's way more than you can use at HF. In fact, you will probably be a little happier with the performance if you put some sort of attenuator at the input.

Keep in mind that any sensitivity below the level of band noise is unuseable. The 602 is susceptible to nearby loud signals, so by attenuating the input you also attenuate those loud signals and are less likely to be affected by the 602's miserable TOIP. Probably the best plan is to attenuate the input until you reach the point where the noise barely increases when you attach the antenna.

I've never gotten huge amounts of audio by jamming the output of a 602 directly into a 386. I've never really tried very hard to solve this, but I suspect there may be an impedance issue here. Take a look at the K1 audio, they use a 386 and a 380 and get a ton of audio.

With the gain of the 602 and the 386, the problem is rarely hearing the signals you want, it's keeping out all the stuff you don't want. A tight front end is a must to keep out the broadcasters, I generally do some sort of a rip-off of K8IQY's 2N2/40 front end as it's pretty sharp and simple. But you will also want to keep the thing sheilded, and of course, with all that gain in a small space, it's going to want to oscillate!

> little recver up and running.. as far as making a transmitter well i'm
sure
> i can figure something out to get a little more power out then 250 mw but
> thats another project...

Take a peek at the NJQRP Club's Fireball 40. They don't sell the kit anymore but the schematics are online. It's pretty simple, only puts out 40mw but they also have a 1 watt amp for it. Another approach for a simple transmitter is the 74Hxx design from the handbook a few years back. Basically, you put a bunch of gates in parallel to select the power you want. You need a pretty stiff output network to whack off the square edges, but that's not so tough.

I have a Pioneer sx939 reciever (1977 or so; 75wpc). It seems to work normally with the exception of this static or crackling sound on the right channel (verified by swapping speakers). The sound is almost like that of a record with a lot of dust or dirt on it. It is independant of the volume, and heard just as clearly with volume completely off. Removing the pre-amp jumpers does nothing to change it. It also isn't affected by which input is selected. Periodically, this crackling will show itself as more of a significant pop.

As a (possibly related) note, the amp seems to be quite hot. The top plate, although you can touch it, is hot enough to seriously think twice about touching. .

Can anyone offer any suggestions of where to start or what to check; or should I just bring it in for service?

Thanks.
Gregg Horan

This sounds to me like a bad solder joint, or internal semiconductor
lead bond or trim pot wiper in the output stage or output bias
circuit. I would bet that if you check the bias current through the
power devices in one channel (check the drop across the emitter
resistors), the noisy channel will have a higher and variable
current. If so, you can tap various components with an insulated
something or hit parts with freeze spray, to find out where the loose
bit is.

Gregg:

I have a Pioneer SX 1500TD that I bought in 1972. It had intermittent crackling on one channel also. I found a bad transistor by tapping and wiggling parts until I found the place that affected the crackling. It was not a cold solder joint...it was internal to the transistor. Replacing it cured the problem.

I have several other receivers/amps but I still use the old Pioneer.

> Thanks for your suggestions and help.

The basic scheme is the half-lattice filter; in this case it's
to of them cascaded.

This sort of filter was common when hams started building crystal
filters for SSB, in the fifties. The best place to find information
about them would be articles from that period about making them,
or books like the ARRL "Single Sideband for the Radio Amateur" or
CQ's "Mew Sideband Handbook" that collected such articles. Back then the
topic was new, so the details were all there. It sort of faded
from view, when commercially made crystal filters became available.
You might find things in more recent handbooks again, though ladder
filters have taken over, because there are advantages of their
design.

I think the scheme saw common useage back then because of the
availability of cheap surplus crystals in FT-243 packages (ie,
cases that you could easily take apart). Then, hams would pick
an IF frequency where crystals were commonly available, and then
grind one or both sets to get them on the needed frequency. Of
course, they were starting from scratch and so picked their
IF to match the available crystals. As I said back in July,
you have to use the IF of the Heathkit, and so you aren't likely
to find crystals on the needed frequency. You'll have to have
them made, and I think you'll have to dig deeper in order to
figure out how to order the crystals.

I'm not going to read through the old articles. I do recall
people saying things like the bandwidth of the resulting filter
would be 1.5 times the spacing of the crystals. But that's rough,
and the better builders would analyze the crystals. You have
the reverse problem; you'll have to figure out the spacing before
you order.

One thing, as someone else mentioned back in July. The simplest
solution would be one half-lattice filter, ie two crystals. The

selectivity would be the same as two cascaded sections, but the shape facter would not be as good. It would be cheaper, but if you find the results less than satisfactory, you may have been better off ordering 4 crystals at the same time, rather than risk the second two not matching the first.

The component values will depend on the filter. The input and output load is going to impact on the filter.

If it's not a transistor problem or or connection problem
then it might be a capacitor.

Most of the old output sections didn't have
a DC coupled output.

The output was at a dc offset.
There was a dc blocking cap in the speaker output line.

I have seen them start to short out.

Other times they dry out and the output slowly
gets less as time goes by.

If it does have them.
Make sure they are in good condition.
If it completely shorts out, it will kill your speakers.
Or nuke your receiver.
Or both.

sounds like a transistor breaking down, strangely common in
transistors of that era ISTR.
use a freeser spray on individual transistors during when the
crackling occurs, the dogey one will probably go quiet when cooled
like this.

You could try looking ex pmr, like NJ8813 and SP8906 HEF4750
there may be quite a few of those stocked around from old service
depots, or if it has to be smd a two-modulus system is very good
SP8792 NJ8821 if you are talking VCO at final freq.
The 4059 is really old.

Hi,

Try making a Colpitts oscillator using Motorola's 2N3947 transistor (NPN).
It's rated to 550 Mhz. Use no hole PCB wiring as well keep the leads as short
as possible to prevent stray oscillations ie use SMT.

John, VA3JRG

And the funny thing is, the amp *can* sound almost normal. I found this in a Zenith stereo back in the seventies; symptom was that it would blow output transistors every two or three *weeks*. The output cap measured four ohms.

I just got into amateur radio (I was licenced at the end of July) and
would like to get into some homebrewing.

What tools do I NEED to get started?
What would be a practical project for someone who's never done any
soldering and has 13 thumbs?
What books would be best for me to get started with?
One book I got from my library suggests starting with "bread boarding" so
I din't have to solder any thing until I was ready to. Is this a good
idea?
Along the same lines, _Nuts_&_Bolts_ has an ad for "snap together kits."
Wouldthis be a good way to get started?

You call QMX Crystals in Texas and tell them what frequency and what
resonance and what load capacitance. You give them a credit card.
Crystals arrive.

ICM also makes excellent crystals but for a lot more than QMX charges.

Several weeks ago I posted a question about how to make a really-good
ground for a new basement which will go under my house starting next
week, but I'm getting innundated with conflicting information, such as:

Some "Gary" wrote:
>The keys to effective lightning protection are surprisingly simple, and
>surprisingly less than obvious. Of course you *must* have a single point
>ground system that eliminates all ground loops....
>The rods should be laid out in a star pattern....

And someone else wrote:
>... create a "ground ring" around the building .... composed of rods
>driven at every 20 feet or so all around the perimeter of the foundation
>.... connected together via #4 or #2 solid copper. Use "bury approved"
>clamps and put the entire thing down below grade.

Now a "star pattern" and a "perimeter ring" are mutually EXclusive!
"Oh, what should I do, what should I do, what should I do?"
(Amahl's mother in "Amahl and the Night Visitors"!)

>.... Never never never daisy chain grounds.....

A "ring" is nothing more than a daisy-chain of ground rods.
"Oh, what should I do...."

Continuing that someone elses instructions:
>.... start the #4 for the ring at that [single-ground] spot, and when you
>get back to that spot continue to the rebar then to the electrical panel.
>One continuous length of #4 is better than a lot of connections.

That's definitely a loop and not just a long, bent daisy chain. And the
"ring" is daisey-chained to the rebar and then the electrical panel.
"Oh, what should I do...."

Some building code I found on the internet:
>3.3 COUNTERPOISE
> Ground the steel framework of the building with a driven ground rod at the
> base of every corner column and at intermediate exterior columns at distances
> not more than 60 feet (18 m) apart. Provide a grounding conductor
> (counterpoise), electrically connected to each ground rod and to each steel
> column, extending around the perimeter of the building. Use tinned-copper
> conductor not less than No. 2/0 AWG for counterpoise and for tap to building
> steel. Bury counterpoise not less than 18 inches (450 mm) below grade and 24
> inches (600 mm) from building foundation.

That's nothing more than another ring with attached star(s)!

Time is running out. Here is how I'm currently thinking I'll make my ground system, and I'd like (authoritative) comments about it:

My house is rectangular, with dimensions of approximately 25 x 50 feet. The completed basement will have four egress windows. My "shack" will probably end up near one of them, and such windows have plenty of wood around them through which I've been told I can run all the wires and cables I want. Furthermore, I've asked the contractor to NOT fill-in four other holes which the house-moving company will use for the large beams which lift the house, and I plan to use the one that's within a couple of feet of where the electrical power and phone lines will both enter the basement as my "ground window" or "entrance bulkhead".

The electrician assigned to my project is willing to work with me, his boss has heard of Ufer grounds, and they have rebar-to-copper connectors, so we're going to put a Ufer ground in all 150 feet of footing.

Then, since I just "happen" to have bought (for only $5!) a large roll of #2 aluminum wire at a hamfest years ago, I'm going to run a perimeter ring along the outside edge of the big hole where my basement will be built (this will be 6-7 feet below grade and maybe 3-4 feet outside the footings), drive ground rods another 8-10 feet deep about every 20' feet around that ring, and use copper-to-aluminum connectors to connect the ring to the ground rods.

Finally, I'll connect the perimeter ring to the Ufer ground at several spots around the house, effectively (I hope) turning the ENTIRE AREA around my house footings into a "single-point common ground". Then I'll connect my "entrance bulkhead" to the nearby perimeter ring/Ufer ground connection point, and that's about the best I think I can do.

Any comments?

Geordi ...

What you NEED, is a small wire cutters, a needle nosed pliers, a couple of screwdrivers, and a small soldering iron. A small meter is almost a must have, too. Although DMMs are pretty inexpensive, I would recommend an analog meter if you can get something halfway decent. There are more occasions where it has an advantage over a digital than the other way around. Look for a high input impedance.

THE absolute, must-have book is the ARRL Handbook. It's not particularly tutorial in nature, but it tells you a little about everything. The projects are mostly not for beginners, but there is enough information that with that book by your side you can pretty much figure out any circuit.

I guess it's probably best to start with a kit or two just to get comfortable with soldering and all that. Here it depends a little on your interest, patience, and tolerance for spending money. A Pixie II (http://www.halted.com/) is a great little cheap kit ($10), and they are a ton of fun. But it can be frustrating trying to make a contact when you're rock bound, so you need to manage your expectations. Another great starter kit is one of the SWL+ series from Small Wonder Labs (http://www.smallwonderlabs.com/). These are quite nice rigs for $65 in kit form (less case). The various QRP clubs also offer kits. The New Jersey QRP Club (http://www.njqrp.org/) is probably the most prolific, and they tend to offer pretty low cost kits. NorCal (http://www.norcalqrp.com/), on the other hand, tends to offer very nice kit, but not as frequently. Also worth looking into are the North Georgia QRP club (http://www.nogaqrp.org/) and the Flying Pigs International (http://www.mpna.com/fpqrp/).

After you have a couple of kits under your belt, I would then try to duplicate someone else's homebrew circuit. Jim Kortge's 2N2/40 (http://www.qsl.net/k8iqy/) is a great little rig, but it is quite a project.

Breadboarding is great for audio or logic circuits, but it doesn't play well with RF. Many, many folks use Manhattan construction for experimentation. See Jim's page above, and the excellent Manhattan construction article by Chuck Adams (http://www.qsl.net/k7qo/). Of course, you can always etch PC boards, but that's sort of a pain for just a test. Unfortunately, as the world moves more and more toward surface mount, it's a skill more of us will need to learn.

Hope this helps a little.

..

Hi Myron,

The first thing you should do is go to the Polyphaser site and read some of the papers there.
Very good stuff on grounding.

You should have more of a ground than just the Ufer by itself. A Ufer should only augment your
ground system and not be the sole ground.

Throw the aluminum wire out! It is not compatible with the rest of your grounding system.
Aluminum buried in the ground and connected to dissimilar metals will cause galvanic corrosion
of itself and the other metal in the system. Aluminum by itself buried will corrode in most soils.
Be sure that no aluminum comes in contact with any concrete. That will eat it up in no time.

All ground rods need to be of the same type of material also. Don't use some copper plated
rods and some galvanized rods. If you do you will have the same problem with galvanic
corrosion.

I assume that your shack will be in the basement? If so then putting in ground rods at below
grade is good. If the shack is at ground level then it would not be a good idea as ground leads
would be too long to be effective. Too much inductance.

Running a loop around the house may be somewhat of a waste as the length of the ground lead
back to your central point gets to be too long to be effective for lightning. Again too much
inductance. You would probably be much better off by running radials out from your central
point in a fan shape to ground rods. Don't forget that a buried radial wire can be just as effective
as a ground rod.

There seems to be a little confusion in some of the posts as to what a "single point ground
system" really is. The thing that you want to avoid is ground loops THROUGH your equipment.
In other words, don't connect your AC ground to one part of the ground

system and your
antenna ground to another part of the ground system. That would give you a loop with the
equipment in the middle. Even if there were other ground wires connecting the two grounds
together, it is not the same point and potential difference can exist with a strike.

Your AC, antennas, phone lines and any other lines coming into the shack should enter at the
same spot. All surge protectors and equipment grounds should be made at one single point. All
equipment grounds should also be connected directly to that same point only. Do not connect
the equipment ground to what may be the nearest ground rod or lead from the Ufer ground.
ONLY connect it to the single point ground.

All ground leads coming from other radial ground rods should go to the single point ground spot
to be most effective. Tying ground rods in a daisy chain become less and less effective the
further away they are from the central ground point. The problem is too much inductance in the
connecting lead. It is much better to go out in a fan shape from the central point.

Ground rods and leads should go out at least several feet away from the building because the
ground tends to be much dryer closer to the building making for a less effective ground. Placing
the ground rods where the rain drips off the roof can help.

I think the brains of the ecofanatics are too hot. I believe it's arrogant
to think man could do anything to destroy the entire earth; and even if
we could, the earth would just kill us off and go back to where it left
off, which is exactly what the ecofanatics want anyway.

So, to all ecofanatics: please stop exhaling all that carbon dioxide
immediately. You're not going to convince us of your good intent while
you're still contributing to global warming.

CRAWLEY MICROWAVE ROUND TABLE

The Crawley Amateur Radio Club will host their annual Microwave Round Table meeting on Sunday, 15th September, 2002, starting at 10am local time.

The venue is at: The Crawley Amateur Radio Club, Hut 18,
Tilgate Recreational Centre, Crawley,
Sussex, England

The entrance to the Tilgate Recreational Centre is located on the southbound carriageway of the A23 just south of Crawley about 200 yards south from the new Broadfield Stadium round-about which is well sign-posted and is close to the Southern end of the M23/ A23 junction at Pease Pottage (Exit 11).

Activities:

1.A bring and buy sale - a large amount of "Silent Key" equipment will to be available (lots of microwave bits, including surface mount components, heliax, connectors, test gear, waveguide, semi rigid coax, and much more)

2.Informal session before lunch.

3.Formal meeting and programme of lectures in the afternoon.

For any further Information contact Derek Atter, G3GRO on Tel/Fax 0293 520424 or on E-mail at datter@btinternet.com

This information has been posted on the newsgroup by

Does Radio Shack still sell that tool kit?

You'll need a decent soldering iron; a roll of solder; a pair of long-nosed pliers; a pair of diagonal cutting pliers (these days, as small as possible...); and mid-sized straight and Phillips screwdrivers. A small vise will be VERY helpful.

>What would be a practical project for someone who's never done any
>soldering and has 13 thumbs?

I would start by buying an experimenters circuit board (or two, or three..) and a few parts assortments at Radio Shack. Don't start by trying to make something that will actually work - start by just practicing soldering parts to a board.

Once you get some practice soldering, I'd buy a LM-386 and the associated parts, and build a small audio amplifier. You can jack a CD or MP3 player into it and show that it actually works.

(Geordi: I think the ads you saw are for something else)

Man, this reminds me of electronics class in high school.

Taught (in the mid-1970s) by a local TV repairman who really didn't understand those newfangled transistors. And taken by auto-shop kids who really didn't expect to pass anything else.

Our final project was to build an "All-American Five" AM radio. Using a bunch of plastic blocks, each containing a single component, and connected with clip leads.

Our instructor told us what each part was for. Until he got to the 200pF capacitor between the plate of the first audio amplifier tube and ground. He couldn't explain what it was for, so he told us not to bother with it.

We all built our radios.

Not a one of them worked.

5,000-watt WTMJ, 10 miles away, not a peep. He couldn't explain it.

I had a hunch. Hooked a 'scope (can't believe we *had* a 'scope!) to the plate of the first audio tube. Sure enough: it had more 3.5MHz RF than my first ham rig.

Grabbed the 200pF cap out of the box, hooked it up, and heard the dulcet tones of Bill Carlson. (they didn't last long, had to find WOKY for the latest Top 40 hits...)

See, that part was there for a reason!

I would agree with Kevin. The first point to address in any trouble shooting endeavor is the power supplies. Electrolytics being the #1 offender and tantalum capacitors used in bypassing DC busses being the #2 culprit. Once the power supplies are primo, the rest of the circuits can be considered.

2247. Copper Wire Stretching?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-14 17:52:34 UTC
From: Dan Richardson <k6mhe@mendolink.com>
Message-ID: <6nt6ou8577hokt0qf0t2q88s0jlb21m8e6@4ax.com>
Source record: 41513

I am wondering if anyone has information on the amount of stretch involved in typical wire antennas using copper wire. Proponents of copper clad steel wire seem to feel that copper wire's (hard or soft) stretching is an important issue. Of course tension and time would play a factor but for antennas such as a dipole are usually under less than 50 Lbs. pull. (Mine are less than 30 Lbs.) So I am wondering just how much increase in length in percentages are we talking about?

Hi all,

I have just acquired a sick Tek 495P Spectrum Analyzer. I have no documentation for this, so I am looking for both Operation Manual and Service Manuals. First choice would be originals. Second choice copies. But even copies of the schematics would be great.

I appreciate any assistance!

Please correct reply-to address to be arrl.net. Sorry for the inconvenience.

Look in some of the ARRL antenna books. There is what is called a stressed parabolic antenna. It is mainly some pipe (maybe electrical conduit) that is layed out like a star with the ends touching each other in the middle. Some screen wire is attachec to it to form a circle. A pipe is put in the center so that it looks like an umbrella. Some strong fishing cable is attached to the ends of the circle and the end of the "handle" . The fishing string is then pulled tight and the antenna is tehn checked to see if the shape is correct.

I just inserted an in-line HF antenna device that reduces signal level by 8-12 dB. I'd like to compensate for this by using an antenna preamp for the HF bands. I'd like to homebrew the preamp. I've been looking at several designs but can't decide. I'd appreciate some recommendations and/or pointers to some sights with good preamps. The receiver (transceiver) used will be an Icom 718.

Thanks, in advance, for any suggestions.

AJ

2252. Help!TEK.SG503 SIGNAL GEN.

Newsgroup: rec.radio.amateur.homebrew

Source record: 41514

Hello! I have just bought a TEK signal generator SG503 through EBAY. I do have very little information. Due to lack of bench space, I was thinking of not using the TM cabinet and power supply and rather build my own supply. Now that I have the unit, it appears to be more difficult than I thought. Two transitors, in the regulated section, one NPN and one PNP are located in the TM cabinet; probably for cooling reasons. I can deal with that by placing them in my own power supply. I am wondering if someone with more technical information and experience with the SG503 can lecture me on possible additional problems. Thanks! Jos, VE2AUC

Stretch is not the big problem with copper wire. Copper work hardens
when it is flexed to the point of yielding (the wind will do this to
the ends of the strand, when the traveling mechanical wave reflects
off the insulator), and after it work hardens it gets brittle. The
steel core in copper clad steel does not have this problem at the
forces created in most suspended strand antennas.

This type of physical leakage is much more common in modern camcorders. DC leakage (passing DC from one stage to the next) was the big problem with Pioneers using those junky Sanyo caps. Power supply bypass is also unlikely to fix anything.
I vote for leaky coupling cap(s) or noisy differential transistor pair.

There will be more stretch if you use solid copper wire. I would rather use stranded, insulated wire for my dipoles. I have one that is 273' over all length, and has not stretched more than a few inches in the last 5 years, even though I have a constant 15-20Lbs. of tension on each end at all times. Stranded wire will flex better, and not snap under normal wind flexing. I use 12ga. insulated to keep the RF from arcing to tree limbs etc., also keeps the wire from corroding.
I tried solid copper once, and it stretched over a foot, then snapped.
As to weather stranded is better than soild in the RF arena, on HF, it really does not matter, it's more about the mechanical part.
Even if the wire is insulated, I still find that 468 divided by the frequency works just as well.

I'm quite surprised that you are unable to find an old C band dish. There are literally thousands of these around not being used. If you live in a smaller town, check with the local cable company. They may in fact have one or two that they can no longer use and would be happy to give away. They may be big, and you may have to fabricate a new frame to use in the concrete base, but they do break down into pieces for transportation.

I use #9 Hard Drawn solid copper wire and have no problems with
stretch even over long periods of time on spans up to 175 feet.
Smaller size wire I am sure would give different results. This was the
type of wire used for W.U. and Railroad Toll Circuits. Lasts many many
years without problems.

I suppose you're already looked into the possibility that the aluminum wire might dissolve in the soil. Doesn't happen where I live, I've seen pieces of aluminum unearthed after many years underground that are still pristine, but how it lasts in soil evidently depends on the alkali content in your locality.

Scott,
Do you know of anybody that might have a copy of the original article
for the flat 8-Ball "dishes"? I think it was in something like Radio
Electronics magazine in the late 70s/early 80s.

Gabrio -

Start your inquiry here:

http://www.ultimatecharger.com/dish.html

"C" band dishes were not extensively used in Europe (for satellite TV) as they were in the USA during the 1980's. Many of these dishes were shippable and you assembled at your site. You may be able to contact a US dealer (or exporter) who would be willing to ship you one.

In Italy, I would check with the regular users of these services (e.g. universities, broadcasting, cable TV, telephone, government, large data service operators - who surplus these items from time to time).

Good luck

w9gb

Fair Radio Sales in Lima, Ohio might be worth a try.

I visited the place when I was in the "neighborhood" last July, and they had a collection of old HP, Tek, military equipment, etc. manuals. Can't comment *how* extensive, but I did find manuals for a couple of my favorite boxes.

Don't recall the URL, but Google should reveal it :-)

Hi Scott,
We had a bunch of those flat dishes in Missouri and Kansas. I recall
they were about 15 feet square, wood frame with mesh across the face.
The feedhorn+LNA/LNB was on a little tripod about 4 feet tall. Actually
they worked pretty well excepting the physical aspects and cows knocking
over the tripod :-)
I saw the article once but I think these were factory-made from the same
people that made the famous 8-Ball Receiver. They were located either
in SE Mo or Arkansas as I recall.
Immediate plan in to be in OH late next week...it keeps changing tho.
Nix on the sked, antenna is down at the moment.

-Bill

yep :-(
in past years here in italy we used C-band dishes for HotBird2, but
just smallest one can be found now (max 1m). Largest ones are already
be dismantled and recycled, rit now....sob!

Now you got *me* interested :-)

I looked at a picture of the 495P and it is a lot newer design than I first expected [in fact, support from Tek just ended at beginning of 2002] so the traditional "vintage" resources (Fair Radio, etc.) may not be a great help.

http://www.tek.com/Measurement/cgi-bin/framed.pl?Document=/Measurement/Service/diystore/welcome.html&FrameSet=service

I can't believe that Tek can't supply the manuals you need by filling out the above form, but you never know these days :-(.

At one point, this outfit evidentally had one for sale [now marked SOLD but maybe worth a try] ----

http://216.239.51.100/search?q=cache:PYATRCjP_KEC:www.harlanlabs.com/specan.html+tektronix+manuals+495P&hl=en&ie=UTF-8

Finally, this company lists it in its inventory, so maybe they can help out ---

http://www.dovebid.com/auctions/production/test_n_measure.pdf

The following are more oriented towards "legacy" Tek (from my "favorites"/ "bookmarks" file ....

http://www.reprise.com/host/tektronix/resources/manual_sources.asp

http://www.geocities.com/r_corriveau/teklinks.html

http://www.repairfaq.org/REPAIR/F_Manuals.html#MANUALS_002

Correcting myself: difluoroethane is not R-134A. I could have sworn I
looked it up a few months ago and saw something that says it is, but
I was wrong.

I probably won't be much help. I can't see why you have a device that causes that amount of loss on HF. Doesn't make sense to me at all. I was thinking the 718 had a preamp already in it. Most icoms do. "both my 730 and 706g do" Not to mention the front end is already hot on most icom rigs. There are many designs for pre-amps that would work, but it's not something I usually recommend. A good way to trash a perfectly good receiver. More images, etc, etc. I once built an HF preamp years ago, and I think I used MPE-152's???'s or something like that. I forgot...All it did was pump up the S meter, and basically trash out an already decent radio. "drake R4". It didn't do a thing as far as improving the s/n ratio. MK

FS CERAMIC/WIRE WOUND RESISTORS
I have a nice lot of 75 wire wound/ceramic resistors. They are
different values and wattages. All checked and marked. this is for the
whole lot.
They are all pretty good size,high wattages. Just what you need
for a good stout amp.
i have a pic.
30.00 + shipping or make me a offer.

FS 2 BIG Neutralizing Capacitors
Two neutralizing capacitors for controling the stability of that
big amplifier project your planning, These are VERY NICE AND BIG.

Capacitors stand 6" high and disk diameter is 2". Both caps are in
very good condition and I would rate at a 8+. There are no pits on the
aluminum or chips on the ceramic.
20.00 each +shipping

well if memory serves the 1057 is programmed by a serial
interface, not that that is a problem but it means a
processor of some sort I suppose, and I think its limited
to about 100mhz unaided. probably loads about as its a
domestic radio chip really. and its probably only got a
definition of about 1khz at LF, depends as ever what
you want it to do.

Free to a good home (UK only, sorry), Marconi Wave Analyser. 0 - 74kHz.

I simply don't want to throw it away if it is of some use to someone.

In good working order.

Ideal for anyone into ELF radio.

I shall be visiting Castle Donnington radio rally on Friday 20th Sept 2002,
so can deliver to there if required.

Contact me off - list if interested.

Has anybody succeeded building a CO2 circuit cooler?
You can buy 'em, but they're way too expensive for home use.
To make this work, it has to change state right at the tip.
Never figured out how to make that work. Always expands at the
valve and only succeeded in cooling the valve.

you need an orifice at the tip

what's happening is that there is nothing to prevent expansion after it
passes the valve

In days of yore, the emergency tire inflators were nothing more than canned butane. In high school I was working in the local filling station when a co-worker was dismounting a tire with a cigarette dangling from his mouth. The explosion destroyed the tire and took his beard off. Amazinly, he was not seriously hurt. Was a heck of a bang though....

I've used environmental chambers that use CO2 for cooling. You use a CO2 bottle with a dip tube, so it exits as liquid, the same as a can of cold spray. The expansion turns it into a kind of snowy spray of solid CO2.

Roy Lewallen, W7EL

Boy, I second Mark and then some.

The noise level on HF is quite high. As long as you can hear the noise, then you have enough gain. Any more gain hurts, rather than helps. Turn on your radio, switch to 10 meters (the quietest HF band) and then plug in the antenna. Does the noise increase? If so, you can't use any more gain. Your receiver has a sensitivity of 0.16 microvolt. Even with your 10 db loss, you probably still have a couple of microvolts of noise coming into the radio. If the signal is below that couple of microvolts, you aren't going to hear it.

Now, what you will do with the preamp is amplify the noise. The signals, being stronger, won't get amplified as much as the noise unless they are very weak, then they will get amplified as much, but no more. So you will hear weak signals as well, and not so weak signals not as well, if the signal you are listening to is the only one on the band.

But it won't be. There will be other signals, and they will be more inclined to swamp the RF amp in the 718 or pump your AGC. You will get lots more intermod (the 718 isn't a K2 after all), so the net result of adding the preamp will be a much harder time, a lot less fun operating, and overall, a big loss in your ability to pick out the weak signals.

Years ago, when tube type receivers had sensitivity in the 5 microvolt region, a preamp made some sense. But with a receiver as hot as the 718, it makes no sense at all at HF.

At VHF/UHF, where the band noise is a lot lower, and the noise inside the radio a lot higher, then it may make sense. But at HF, it's pretty much always a looser.

..

You did not say which frequency band you are interested in.

If you are interested in the 21 cm hydrogen line or shorter wavelengths, you might consider using four 1.5 m dishes on a rigid frame and feed the signal with coaxial cables of equal length to a combiner and then into a receiver, producing an equivalent collecting power of a single 3 m dish. You might even consider using nine 1 m dishes for the same effect.

At 21 cm you could still use coaxial line 1/4 (or 3/4, 5/4 etc) wavelength transformers to transform the impedance from four 50 ohm antenna elements to a single 50 ohm downlead using a 100 ohm section or first pairing two 50 ohm antennas to a single feed using a 70 ohm section and then pairing these two lines into a single downlead with other 70 ohm sections. Unfortunately, these 1/4 transformers are frequency selective and they work only on a narrow frequency band.

Actually, I was off on my initial 8-12 dB loss. It is more like 4-6 dB. The in-line device is an interference canceller, similar to the MFJ model, except home brewed. There is some loss, but I found that the orientation of the noise antenna makes a difference in the amount of total loss. It seems to work great on computer screen noise, but the power line noise I really wanted to eliminate is not even touched. Maybe the noise is too broadbanded (when the noise occurs I can hear it on all the Ham bands) . The Icom blanker won't eliminate it either, but the noise blanker in an HTX-100 10 meter rig eliminates it almost completely! I agree with posters that a preamp would definitely do more harm than good. However, my immediate goal is to get rid of this noise!

2295. Repairing Conductive Rubber Touchpads

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-16 02:28:08 UTC
From: Terry Nixon <TLNixon@mchsi.com>
Message-ID: <Ykbh9.332644$aA.58301@sccrnsc02>
Source record: 41458

Has anyone ever had any success at repairing these?

I have 2 Kenwood HT's and an Azden 2 meter rig that I'd liek to respore to operating condition. The pads have simply worn out.

I know MCM Electronics sells a kit to repair these, however it is about $25.00. Does anyone know if the stuff works or not, or maybe if someone else has a similar product?

Thanks
Terry-WB0VQP

I've just posted the Tek 495P operator's manual at
http://www.qsl.net/ke5fx/misc/495p.pdf. 17 megs, 160 pages.

I may have a spare set of service manuals lying around -- I'll have a
look tonight. I'm not in the manual business by any means, but drop me
a line if you can't find them for sale anywhere else. :)

Also, I'm pretty sure you can rent the service manuals from Consolidated
Surplus (http://www.consolidatedsurplus.com).

What are the trouble symptoms? That's a heck of a nice piece of gear if
you can get it working.

Source record: 41460

Hi All,

I know this has all been discussed before, but I have searched Google to try and find relevant info without great luck.

I'm looking for a cheap and simple design for a homebrew solid state 6 meter 100W SSB/FM linear amp that will operate from 13.8V supply and 10W (or less) drive. I believe QST had such an amp detailed in October 1990 issue, but I don't have access to any QST (or similar) magazines so that isn't much use to me!!

Any info, diagrams, etc would be greatly appreciated. Thank you.

Considering the typical cost of a service manual today, ordered
from the company that produced it, that's a heck of a good price.

Manuals Plus has several copies for an even better price ($25.00).

The noise eliminator should wipe out power line noise as well - assuming
that the source is close enough that it can be received by your sense
antenna.

If it can, then you must be doing something wrong in adjusting either
your phase or gain of the inverted signal.

I can eliminate computer and monitor noise completely, but it won't touch the power line noise. Of course, I've only been using a 5 foot piece of wire as the cancelling antenna. Perhaps if I went with a larger antenna, I might get results but then I don't want to start cancelling the signals I want to receive.

> If it can't, then you must be doing something wrong in adjusting either
> your phase or gain of the inverted signal.

The power line noise is apparently some distance away because no adjustment will affect it.

Yep, I understand the thermodynamics. The problem is mechanics.
What I don't understand is how you
get the valve in your hand and the end of the stick far enough away so you
can get at the thing you're spraying and still have the expansion happen at
the tip????
If you rely on the orifice at the tip, you have to fill up the whole tube
(between
the valve and the orifice) with liquid at each
spray and it will spray for a good long time after you shut off the valve.
Not very good
control. The only way to emit less than maximum cool is to close the valve
part way.
This allows the pressure in the tube to go down and the phase change happens
in
the tube cooling it instead of the thing you want cooled.

One possibility is to have a tiny valve right at the tip with a mechanical
contrivance
to allow you to open it from inches away. I can't get a picture in my mind
of how one
would accomplish this.

Instead of using a valve, why not do as is done in most domestic
refrigeration units and use a small capillry tube for the metering
device. That would eliminate filling up a larger tube to get the
cooling to where you want it.

Thanks for that info. I've had a look at the site, and while the pcb is a tempting idea indeed (makes construction real easy), by the time I figure in currency conversion, postage, etc I'm looking at around $50AUS just to get the board. If possible, I'd be happy just to get a copy of the article so I can see if it's suitable first, and maybe homebrew a bit cheaper.

Cheers

My Zenith TV uses something similar. I rub the rubber keys on some fine grade sandpaper to remove the tin that gets on the rubber. I don't rub hard as I don't

want to remove the rubber. It works fine for a few months between cleanings.

Good luck.

Buy a 100 ft reel of Belden 83265 cable (RG-178B/U).
Attenuation at 50MHz 10.5dB, 100MHz 14dB, 200MHz 19dB,
400MHz 28dB,1GHz 46dB.
Doesn't matter what, if anything, you connect at the other end.

I've tried the repair kit, and in "my" experience, it didn't work.
I did 2 keypads to the letter of instructions, with no luck.
In my opinion, they aren't worth the cost.

i have made something like sstv over internet. or lets say echolink
for sstv. the test-version is not very elaborate or user friendy,
but it seems to work.

the url:
www.hb9tlk.com/isstv/
just press "download" if u dont understand german.

soft is based on the mmsstv.dll module.

I didn't think the can of air for my "spare" was butane. I will check. Since my spare doesn't come apart, I guess it would be safe. I had purchased cans in the 80's made for flat fixing that were flammable Now they may be hard to find or do not exist due to restrictions. Tire places are extremely cautious about those situations. Some think ALL tire inflators are flammable. Perhaps thats the safe assumption.

I wonder if one could make a low flow cooler using a thermo cooler??
Those freeze sprays are usually too cold anyway.

Last time I bought a can of tire sealer, I got a sticker to put on the rim near the valve to warn the person fixing the tire to not smoke and to inflate and deflate 3 times or so. It contained butane and this was less then 6 months ago.

2314. Need help with pulse transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-17 02:46:46 UTC
From: hexter@blazenet.net
Message-ID: <uod5smf2agbo7f@corp.supernews.com>
Source record: 41477

I need 1900v at 2.75a for .25ï¿½sec at a rep rate of perhaps 1000hz.

I have extracted a 'flyback transformer' ferrite core from a television of perhaps 19 inch size. I have stripped to just the bare ferrite core.

Here is the situation, I would like to 'charge' the core from a 12vdc source, with a transistor to ground. I am thinking the primary would be perhaps 20 turns of #14 wire. The 'on' time of the transistor will be 50ï¿½s, with an abrupt turn off. I am guessing that the 'inductive kick' of the field collapse will give me more output voltage on the secondary winding than what a simple turns ratio would indicate. Lets say the secondary was 500 turns. The primary was 12/20, or about .6v per turn. This would suggest a 300v output from the secondary, but I am guessing I would see more. (perhaps much more)

Can anyone make any suggestions, or offer any input as to if I can actually get enough output from this simple circuit to pulse a very small marine radar magnetron.

Thanks from WN3SOH / WB3BIO / KD3SH

Your optimism is not well founded. If the windings were perfectly
coupled, then the voltage per turn would be consistent between the
ones carrying the low voltage DC and the extra ones that only carry
the output. With less than perfect coupling, the extra turns will see
a bit less volts per turn than the driven turns. Sorry.

The transistor will have to withstand its fraction of the 1900 volts
total (based on its fraction of the total turns) and a bit more to
account for the energy that is not coupled between the driven and
output turns..

I'd like to build a noise gate circuit for my HF receiver, to be located externally between the radio and antenna, but I'm not sure how to wind the toroids. The circuit I'm going to use (unless someone can suggest a better one for HF use) is at
http://www.lwca.org/library/articles/jtreed/gate/gate1b.htm

This uses two FT50-75 toroids and I understand I need to change these to FT50-43 for hf use (1.8- 30 Mhz). For 50 ohm input/ ouptut, how would I wind the toroids using 43's?

Thanks,
AJ

I fix heaps of them as TV VCR remotes etc - it sounds brutal but this
works 90% of the time.

1. Dismantle keypad (rubber)
2. Remove circuit board.
3. Dump both into a sink full of hot water and dishwashing detergent,
scrub with toothbrush, rinse thoroughly with clean running water.
4. Let dry well (and be careful of water underneath IC's and ceramic
resonators) and all should be well. If in a hurry, use wifes hairdryer
to speed up the process.

The main failure mechanism is not wear, its finger grease/coffe spills
etc contaminating the surfaces.

If this doesnt work, then the 2 pack silver/epoxy mixes do work - but
they are one shot, so have every crook remote in the house ready to do
before it goes off.

Hope this helps.

Yep! That works.....I've done that too. Around here, for a shop, it's not worth the effort. People are too cheap to pay to repair OR to buy a new unit....So, I use these tactics mainly for myself. Even then, it's on a limited basis.

But you're right about the causes... Grease from fingers, especially the result from handling the remote while eating potato chips or other greasy foods, coffee - pop - beer spills, dust, etc. Remote killers. Oh yeah, cigarette smoke, and some other things too!

I merely replied to the man's question based on my own experience regarding the product in question.

Don't you know it. As an experiment, try cooling some individual components--especially semiconductors--on a *working* circuit. One can completely shut down a perfectly functional device (usually temporarily) with freeze spray. I guess there's an art to using it....

But, of course I am speaking of the 'flyback' pulse of energy released
at the collapse of the field, which will be a far faster rate of change,
and will give me a pulse output exceeding the turns ratio, but
consistant with the calculated change in flux per second, verses turns.

In other words, there isn't 25,000 turns of wire on a flyback that
produces 25,000 volts, and I am speaking of the old 'non-tripled'
h.v. supplies. Have you ever looked at the actual turns ratio of pulse
transformers?

How much power? (The suggestion of using a length of lossy coax is a
good one, especially if you have some kicking around anyway. But you
might need to use larger coax first to get the power down to a level
that won't melt the little coax. OTOH, if you are only trying to
dissipate 5 watts and want something small, there are other ways you
might want to consider.)

Cheers,
Tom

2323. Navstar Systems Ltd - Timing GPS Receiver info

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-17 20:28:52 UTC

Hi All,

I bought on a surplus market a GPS receiver made
by Ericcsson with the Navstar Systems Ltd GPS Receiver boards
inside.

It is completely enclosed on a waterproof plastic box
and is called "Timing GPS Receiver". It is new (never used)
packaged in original box. It was made around 1997.

There are three boards: GPS receiver RF board, logic unit with
have many IC's including a Motorola MC68EC020 CPU and a
MC68882 FPU, etc., and a I/O PSU board.

The I/O board has only a three pin power connector and
two connectors for optical cable interface.

There is no ovenized crystal oscillator inside, and I think that the
1PPS signal goes through the optical interface.

I also searched into the web for information but I found nothing !

If anyone has information about this receiver please help.

You can see photos of this strange object here :

http://www.qsl.net/i6ypk/navsymm_gtr.htm

Thanks and 73.

Things that are generally conserved at the moment of turn off in this sort of thing are amp turn and volts per turn. So if you apply 10 amperes to 10 turns (with your low voltage supply, through a transistor) for a total of 100 amp turns) and the output is taken across 40 turns, then the current through those 40 turns will be 100 amp turns divided by 40 or 2.5 amps. In order to achieve 2000 volts across those 40 turns (or 2000/40=50 volts per turn), the driven 10 turns would have to allow an off state voltage of 10*50 = 500 volts. All this assumes perfectly coupled turns, so an actual pulse transformer will put out just a bit less current, and force just a bit more primary off state voltage. There is no free lunch. Producing a 2000 volt pulse that supplies amperes is no small task.

> Lou/Tech@DP.NET

Hi Lou,
yes, you are right, most of the repair kits dont work! - the exception is the 2 pack epoxy one - its made in USA, so if you are really interested I can dig out the details for you. I charge $35 fixed price for a remote repair, and for the expense LCD screen ones that cost a bucket to replace the customers usually do it. A hell of a lot of new consumer stuff relies on the remote working to do virtually everything except turn on the mains power, so the customers are stuck without it. I also keep every dead remote I get to rat for parts, so all in all its profitable, but then I dont know what the costings are where you work, it might be more economical to replace.....

2326. Fox Hole Radio

Hello

I am looking for info on a fox hole radio. Using a razor blade, pencil lead, ear phones, and wire.

What razors and what pencils work best. And how much wire?

Thanks

Mike WB2GLW

I find that a 45 ohm resitor with a 5% tolerence from RS works fine on 6m-70cm.
Of course it's on a homebrew rig...

There is plenty of DOS left in Windows, just make a boot disk!

Hmmmmmm... The photos lead me to believe that the optical fiber
ports may be hitched to an internal Ethernet transceiver operating
10Base-FL.

Have you tried treating the thing as though it has a TCP/IP stack,
and talking to it via LAN? Or perhaps just sticking a packet sniffer on
its output side, and watching for NTP or SNTP packets? It might be a
self-contained time server.

Good luck in any case.

This is most likely due to condensation, I think. Unless the board is
squeaky clean, spraying freeze-mist onto it will have the effect of
instantly drenching it in a conductive aqueous solution of
who-knows-what.

Take your basic crystal radio design and substitute the lead and razor
blade for the crystal. I suppose any ole #2 pencil will suffice but the
razor blade might be a problem. The older razor blades had the brand
name lightly etched into the metal and it was at this spot where the
corrosion could be counted on for detection.
But heck, still worth a try. There should be some project diagrams on
the web.

Hello,

I'm looking to return to amateur homebrew through a "little" project. I'd like to combine my computer hobby with amateur radio using packet. A while ago, I used a 2M HT w/ an AEA PK-88 for 2M packet. Now, I've seen a lot of low-cost, highly integrated RX/TX IC's... some of which even have packet mod/demod on them. Does anyone know of any (relatively) simple 2M packet radio designs based on any of these chips?

Thanks.

in digital circuits, it's very common to use freezer spray (or a hair
dryer) on a circuit where timing marginality is suspected (e.g.
setup/hold violation). It's more appropriate when there are many
discrete components, where changes in temperature will tip dodgy
timing over the edge - and you can see which component is having
trouble.

You can get any of the obscure AD stuff direct from them on the web. It
costs, but is pretty easy. I've got DDS ICs and the IF amps for the
Bill Carver IF this way.

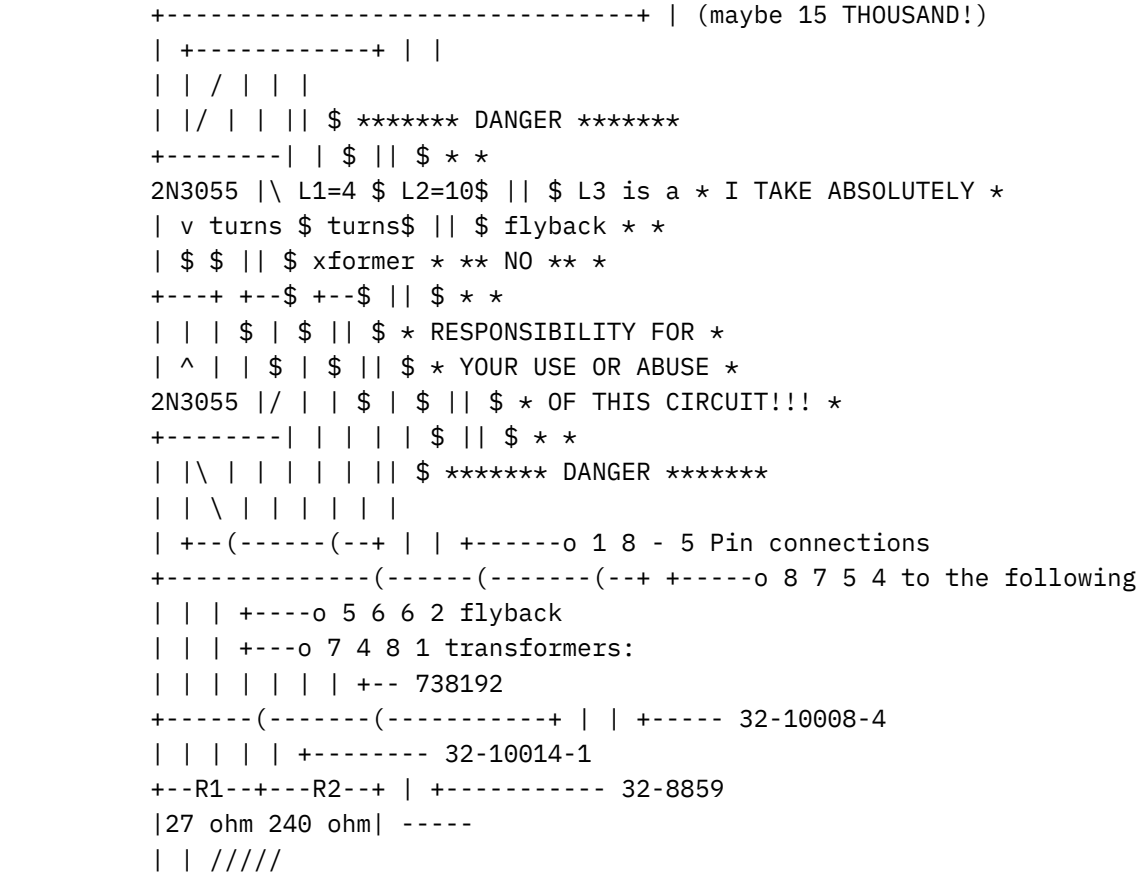
Here is an old post that may help:

---------- cut here ---------- cut here ---------- cut here ----------
Article 7732 of sci.electronics:
From: mac@cis.ksu.edu (Myron A. Calhoun)
Subject: Tesla coil schematic...

While cleaning up my workroom I found a schematic for a "TESLA COIL KIT"
sold (many years ago) by B & F Enterprises, 119 Foster Street, Peabody,
Massachusetts 01960 (617) 531-5774:



- 12 volts +

Quoting from the instructions:

"WE TAKE NO RESPONSIBILITY FOR YOUR ACTIONS!!!

The new windings must be added to the flyback transformer to allow adequate transistor drive capability. These windings are hand wound on the bottom leg of the ferrite core where the original filament winding was located. Remove and discard the original filament winding. In its place, wind first a ten turn, center-tapped, winding using approximately 30 inches of #20 or larger hookup wire. This is easily accomplished by winding five turns at one end of the core and then twisting a loop in the free end before adding the second five turns. The complete ten-turn winding should then be held in place with a turn or two of electrical tape with the two ends and the center loop all protruding. Connection can be made to the center loop when the insulation has been carefully removed. If it becomes necessary to cut the center loop, be sure that the two ends are scraped and joined to form a mechanical as well as an electrical center-tap to the winding. [L2 in my drawing]

"The second winding should be wound directly on top of the first but it should only have a total of four turns--two each side of the center-tap. Again, wind two turns of #20 or larger hookup wire, pull and twist a center loop, and wind the other two turns. Tape this winding in place on top of the first. Do not let the center taps of two windings touch each other but they should not be more than one quarter of an inch apart. [L1 in my drawing]

"Wire the modified transformer to the transistors and the bias circuit resistors as indicated on the schematic circuit diagram. Be sure to mount the transistors on a suitable heat sink with the insulating hardware provided to protect them from over heating. Since the collector connection of these transistors is made to the case, it is necessary to keep them electrically isolated from one another and from the heat sink and insulators are provided to allow this. Heat sink area of approximately 25 square inches should be adequate. If, however, the power transistors become too hot to hold a finger on, more heat sink area should be provided. Heat sink material of one-eighth inch aluminum is desirable.

"Note: If Oscillation does not start Immediately Interchange the two Transistor Base connections [capitalization as in original!]

"CAUTION: LETHAL VOLTAGES ARE INHERENT IN THIS DEVICE. EXTREME CAUTION MUST BE EXERCISED TO KEEP THE FULL OUTPUT OF THIS DEVICE FROM BEING APPLIED LIMB-TO-LIMB OF ANY LIVING ANIMAL. SEVERE BURNS OR DEATH MAY RESULT FROM CONTACT WITH THE FULL OUTPUT..."

There were other instructions about how much damage might accrue to a human if contact were made to the high-voltage output, so BE CAREFUL!

I used one-half watt resistors for R1 (27 ohms) and R2 (240 ohms) and
got a nice Jacob's ladder effect. It also wiped out most of the
computer terminals in the entire building, so I couldn't run it very
much! I later tried 18 volts and one resistor zapped immediately!

---------- cut here ---------- cut here ---------- cut here ----------

Mike Harris wrote a follow-up:

---------- cut here ---------- cut here ---------- cut here ----------
Article 7801 of sci.electronics:
Subject: Re: Tesla coil schematic...
Date: 19 Feb 90 18:51:04 GMT

2343. UHF signal to noise problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-18 17:51:38 UTC
From: daniel000@prodigy.net.mx
Message-ID: <26692055.0209180951.43f5531f@posting.google.com>
Source record: 41406

Hi,
I am living in Mexico, a friend across the Bay (2.8 miles no obstructions, sea level) needed phone/Internet service so we ordered a CE338 from (now out of business but the website is still up)

http://customelectronics.tripod.com/phones-cell/CLCE388/CLCE388.html

The stats are.....

UHF band 265 - 395 MHz

Watts- 5w + 5w only.

High gain antenna with 100 feet of low loss 5D cable on both the base and remote unit and have a good amount of space around both antenna. (You can see the antenna we are using at the bottom of the custom electronics web page I gave above).

US Robotics 5686E external modem.

The Ati11 command on the modem reports a Signal to noise ratio of 27.

I have very little experience in the area of UHF radios and we are having trouble finding anyone in the area who does. (I did work on the Avionics, navigation and auto pilot of Cobra Gunship's in Vietnam for two years so I remember a bit of that).

The Exporter of the CE338 is My China Biz. (www.mychinabiz.com) They call the unit a CL398 and he (Martin) told me it has a compander. Other than that they are not able to give me any information like a manual or tuning recommendations.

We are connecting to the Internet at apox. 19 kbs but we are having trouble getting consistent performance out of it. The telephone part works fine but I can hear a little bit of a hiss in the background. I don't think there would be a problem taking the compander out as we are in a very remote area of Mexico and there really arent very many laws here to begin with. But from what I have read the compander is probably reducing the noise level due to the reduced bandwidth.

I am thinking it must have something to do with the low signal to noise ratio or else we are on the edge of the range even though the supplier states that it has a range of 45 miles.

I was going to switch to a higher quality coax cable (if I can find some) and get the transmitter/receiver as close to the antenna as possible and or change the antenna, I don't really know what to do, that is why I am posting this.

Any assistance is greatly appreciated. Thank you in advance.

Sincerely,

Daniel Hallas

My hunch is that you should have a dead quiet signal at that
power/range. I can't tell anything about the 'hi-gain' antenna from
that photo on the link. Is it a yagi or directional antenna of some
sort? If not, it should be.

Can you find a ham/marine radio tech in the area that might have a VHF
wattmeter that could evaluate whether or not the gear is putting out
properly as well as for evaluating the feedline loss and antenna match.
Any (or all) of those factors could be the culprit.

Another thing to consider is your net connection. Additional noise
plugged into the 'loop' will magnify the problems of a connection that

is less than good to start with. But, that being said, I still don't think the basic 2-mile phone link should be noisy.

Hello,

I'm looking for some resources about selecting an IF frequency for a receiver. I'm looking at the idea of building an upconverting HF receiver which would convert the HF signals to a high IF (>100 MHz), perform wide filtering there, then directly convert it to baseband I and Q channels for demodulation via DSP. I'm trying to figure out what some standard high IF's are... I've seen the rule of thumb regarding at least 3 times the maximum frequency to be received, but looking for more specifics.

Unless it is an unusual situation you do not need an antenna tuner. If
there is enough swr that a tuner is needed on 2 meters and up , you will be
loosing a lot of power in the feedline.
Change or do some work on the antenna.

Hi,

This isn't going to help you much but VHF/UHF paths
across water can be a big problem - even ones that are line
of site. I know of at least one drop-out on a particular
military circuit due to this. Depending on certain
propagation factors or seasonal conditions the signal can
bend vertically mid-path causing a high BER. I wasn't the
project engineer on the circuit (fortunately) so I don't
know the final outcome. Of course the route was planned
without a proper survey being carried out. This was in the
Middle East where similar temperature and humidity levels
as yours prevailed.

I can't imagine a reason for a rule of thumb like that, plenty of HF rigs with a 45 MHz first IF, and plenty more with a 70-75 MHz first IF. Pick one where you can make/get a suitable filter.

The up-conversion is going to limit your performance from a oscillator phase noise standpoint in a BIG way, Continuous coverage won't help it either. Further, you might wish to look at mixing products before you jump.

I'd use 70Mhz. Common in many high end commercial receivers. Lots of designs/components are available for this IT. You might also consider 45 mhz, another popular IF.

Something that would help in figuring out the expected range of the system is how high the antennas are on each end above sea level..... Since you are going across water, height above sea level is the main thing to be concerned about.

If they are close to sea level, going across 2.8 miles may be difficult. There is quite a bit of loss by ground absorption and that all depends in now high the antennas are.

The claim of 45 miles by the manufacturer for this sort of system is usually the theoretical range if each antenna is up on a mountain top.

Technically, yes, they can work that far, but in the real world the usable range is a heck of a lot less.

Marketing people love to use the absolute best claim they can make and this sort of unreal distance is often seen on wireless LAN, cordless phones, and so on.

But unless you plan to build your own roofing filter, you need
to pick a frequency that you can get a filter for. And if you're making
the filter, the higher it is the wider it will be, and the harder it
will be to make.

The choice of IF frequency is important in terms of image rejection.
Too low compared to the signal frequency, and you'll have to do
a lot of front-end filtering.

If the IF frequency is too close to the signal frequency, you may
have feedthrough problems (ie the signal from the antenna goes
straight through the mixer, and gets into the IF. And having the IF
right in the middle of the tuning range may bring about some other
problems.

Likewise, if you pick an IF frequency that is used by a strong
signal, that signal may get into the IF.

Choosing an IF frequency may also be related to the sort of
local oscillator you are using. The bigger the difference
between the signal frequency and the IF, the higher the oscillator
frequency; certainly in the days of free-running local oscillators
this would tend to make a drifting oscillator.

For an HF receiver, probably anything above a few MHz would make
for easy image-rejection. Receivers with 9MHz IF's have been
around for forty years or so.

With ham band receivers, rather than general coverage, such an
IF frequency didn't get in the way of the tuning range. One reason
to go higher was to get the IF out of the tuning range for HF general
coverage receivers.

So in tuning an IF frequency, you basically have two issues. What frequency can you get a roofing filter for (or easily build)? And if you've got choices, you run some calculations to see which of the frequencies would put the least spurs into the desired tuning range. And if you've got choices, you should give consideration to which might make for easiest design.

45MHz filters seem to be a common frequency in surplus circles. I've seen filters in that general range used in cellphones (and the phones usually come with a crystal to drop that IF to 455KHz). I've also seen filters in the 70 or 80MHz range in other cellphones.

You might want to buy some older cellphones (the bulky kind that sell for fifty cents to a few dollars at garage sales and church rummage sales), and see what turns up.

But you might also want to give thought to whether you need such a high first IF. If you can live with the IF in the HF range, it may simplify other parts of the design, and you're likely to have a better range of choices of available filters, not just in center frequency but in bandwidth. If you don't need FM-bandwidth, you can go with a narrower filter at 9 or 10.7MHz, while something higher in frequency is likely to be at least FM-bandwidth.

A growing number of people in the UK have purchased ASCOM SE550 4m Radios from the Rugby Amateur Transmitting Society, who still have a substantial number of units available!

Some technical information, circuit diagrams and manual sections are now available on my web site:

http://www.blob.demon.co.uk/

For those not familiar with the equipment the overall specification of the unit is:

Frequency range 68-88 MHz
Channel spacing 12.5 KHz
Mode FM
Antenna BNC 50
TX Power 25W
Deviation 2.5 KHz
DC Power Nominal 13.2V (10.8-15.6V) (RX approx. 1A, TX 6.5A/25W)

The units supplied by the Rugby Amateur Transmitting Society are modified, programmed and working on 4m.

N.B. I have noticed a number of these units being resold on EBAY for considerably more than they were purchased for!

Take any antenna tuner intended for the 20m band and divide both the inductances and capacitances by 10 :-).

But seriously, why do you want to use an antenna tuner on VHF/UHF bands ?

While the use of an antenna tuner on HF may be justified due to the relative width of the bands e.g. 13 % for the 75/80 m band and the extremely high length to width ratio (and hence narrow bandwidth) of wire antennas. In this case the antenna tuner tunes both the antenna _and_ feedline into resonance.

On VHF/UHF the relative bandwidth is smaller and by using thicker tubing and folded dipoles, the antenna bandwidth itself can be made sufficiently wide. Since the feed line losses are considerable at VHF/UHF, trying to resonate the feedline _and_ the antenna with an antenna tuner down at the transmitter, even larger losses will occur.

If you really need an antenna tuner, which I doubt, it should be mounted at the antenna and be remotely controlled, unless you want to climb the tower each time it needs to be readjusted. By this arrangement only the antenna is tuned and the feedline is not resonated, thus keeping the feedline losses down.

It depends how you define line of sight :-), it might be something
else than you would simply expect from geometry.

If you have optical mirages, you most likely have radio mirages and
the signal is coming or going in unexpected directions.

>I know of at least one drop-out on a particular
>military circuit due to this. Depending on certain
>propagation factors or seasonal conditions the signal can
>bend vertically mid-path causing a high BER.

I assume that this was a UHF/microwave link which usually have a quite
narrow antenna pattern so the transmitting antenna does not
"illuminate" the receiver antenna in all weather conditions, but below
or above it. The same applies to a narrow beam width receiver antenna,
since during a mirage, the signal is coming from an unexpected
direction, thus effectively, the antennas are not pointing at each
other at these times.

Having a broad antenna beam at least in the vertical direction will
reduce such problems.

The optimum height above the water level varies from day to day and
frequency to frequency, since the multipath nulls caused by "ground"
reflection varies all the time. In such situations space (vertical)
and frequency diversity may help. In extreme situation only an antenna
highs of 1-5 m above the water may be working.

However, in this case with less than 5 km distance and with
frequencies in the lower UHF and thus quite broad antenna beams, I
don't think this is going to be a problem, unless you are frequently
seeing fishing boats high in the sky.

An other reason for a high first IF is that the relative frequency range required by the LO is greatly reduced. With an IF of 45 MHz, the LO only needs to tune 45 to 75 MHz, which is well below an octave, so a single VCO within a PLL could do this. Unfortunately, such wide PLLs usually have a very bad phase noise performance, so you have to split the tuning range of the LO anyway to get a decent phase noise performance.

The third appeal for a high IF is that with a sufficiently strong mixer, no tunable front end selectivity is needed and all filtering that is needed, is some fixed low pass filtering at 30 MHz to keep the image frequency out. Unfortunately finding sufficiently strong preamplifiers and mixers may be unrealistic and thus, many wide coverage receivers have filters that are one octave wide (or narrower) before the mixer. Such bandpass filtering keeps out the mixer harmonic distortion of signals at f/3 and f/5 from reaching the receiver.

If you have to split the LO range due to phase noise and split the input frequency range due to signal handling problems, you have to ask yourself, is the high IF general coverage receiver so appealing as it would appear to be at first sight.

Why have an IF at all? Since you're using I and Q signals to phase out the opposite sideband you can just use direct conversion. But you may have a problem with the range of the oscillator if you are looking for a general coverage receiver.

Some years ago I saw a review of such a tuner (probably in RadCom). I don't
think many were sold, though, and it wasn't in production for long. It
sticks in my mind, because the reviewer managed to match a dustbin to the
radio. 8-)

>
Actually it was tankers waiting in the roads to come alongside buoys
to take on oil that seem to hang in the air - not bad for 250,000 tons.

As for frequencies where strange things occur, I have experienced a
basic simplex circuit, somewhere in the military 30 - 88MHz band, where
you frequently couldn't work whip-to-whip along a 5km path that was
optically visible from both ends (albeit if you stood on a 2-storey
roof). In fact Plessey used to make an on-frequency repeater to try to
eliminate such 'holes'.

As far as I can see, the antenna in use in the Mexican location
appears to be an omni-directional vertical which wouldn't be my choice.
The stated SNR is 27:1 (14dB) which should easily be sufficient. This
seems to me then to implicate multi-path distortion.

Anyone know where there are tutorials on scavaging Rf parts? Of course, i'm new to Rf & have a few old RC cars & would love to use those parts to build something new.

Any suggestions?

Choose an IF where there isn't likely to be a strong over-the-air
signal. If a local signal does get through your front end or IF strip
shielding, it will interfere with ALL receive frequencies (because
it's going directly to the IF). 100 Mhz is in the FM broadcast band,
and would not be a good choice in that respect. 45MHz is below the old
49MHz cordless phones, 6M amateur band, and (US) television channel 2:
a reasonably quiet spot. 75MHz falls in the gap between TV channels 4
and 5, another fairly quiet spot.

There can also be problems with water reflections changing with the height of the tide. Unlike mirage effects (tropospheric bending), variable sea reflections are a problem every day.

A possible cure is to tilt both antennas upwards, which will attenuate the sea-reflected ray much more than the direct ray; but whether you can do this will depend on the signal/noise ratio.

In some places in Scotland, all the UHF TV antennas are at ground level so that they can see the transmitter on the mountain, but they can't see the variable sea level in between. TV antennas on 2ft masts look totally weird, and you have to be *so* careful not to trip over them!

If your 2m SWR is high enough to require an antenna tuner, it is so
high that you will lose a lot of your transmitted signal unless you
are using very expensive coax or unless you put the tuner at the antenna.

Jacques

Feedline losses at HF are fairly low. At VHF, even fairly expensive feedline has considerable loss.

When you put an antenna tuner between point A and point B, it attempts to match the SWR between those points. If you put the tuner between the feedline and the transmitter, power will be effectively transferred into the feedline.

However, the feedline still has a characteristic impedance of 50 ohms, so there is a substantial mismatch where the feedline meets the antenna. This mismatch causes the current on the feedline to be higher than it would if it were matched. This higher current causes the loss on the feedline to be higher, depending on the degree of mismatch, perhaps many times higher.

At 80 meters, I might have a feedline characteristic loss of, perhaps, 0.3 db or so. Even with a fairly astronomical SWR, it might bump that up to 3 or 4 db, measurable, but not really noticeable.

At VHF, however, that same feedline loss might be 2 db to start with (25 meters of RG-8 solid dielectric). Given the same SWR at the antenna, the actual loss might be 20 db, certainly not something that can be ignored. If you are asking this question, you might be using an even smaller feedline. At 2 meters, 25 meters of RG-58A has a characteristic loss of almost 6 db. Hit that with a significant SWR and almost all of your power is being used to heat the coax!

So at VHF, there are a few different strategies that folks have suggested. The most obvious one is to make the antenna resonant in the first place. At 2 meters, a dipole is barely over a meter long. Few people face such space limitations that they can't get a meter of wire in the air. Another approach is to put the tuner at the antenna. This solves the problem of current on the feedline, but it means that you often need some sort of remote control to adjust the tuner, unless you will be operating over a limited frequency range. The third strategy is to get feedline whose characteristic loss is lower. Depending on the length of your run, this can be an expensive alternative. You are typically talking hardline which can easily cost 10 euros per meter or more, and which is a pain to install, or some sort of purged system which could run into many thousands of euros.

This is why so many folks said, why not just make the antenna resonant in the first place.

Now, all that being said, suppose you have a system where the SWR over the range you want to operate is, say, 1:1 at the center, and 2:1 at the edges

of the range. I would suggest just ignore it, presuming you measured the SWR at the antenna. There's another gotcha here that is more of an issue at VHF. If you see 2:1 at the transmitter, and you have a fairly typical feedline, then the SWR at the antenna is much higher. Those same losses are making the SWR at the transmitter appear better.

Hope this helps

..

I saw the schematic fine also. I would not recommend this circuit. It's simple, but the crystal drive is so high that the transmitter would probably chirp all over the place. I had the same experience with the 6DQ6B circuit in a later edition of the handbook. It is best to have a separate oscillator circuit with a buffer and then drive the 6146. I would also advise getting a VFO, if possible, as a xtal is very limiting to say the least. I had two xtals when I was a novice and spent a lot of time calling CQ with no answers. I had fun anyway, though. :-)

Happy Trails,
Steve WB4CZR

Sure, I have built superhets with frequency counters and even variable bandpass tuning, most of my own half hazzard design, and they worked quite well. I enjoyed every minute of it, and now Im just trying to make something work reasonably well with as few parts as possible. I guess you could say I like doing things that not many others have done before. I see that no one has any constructive words to say on this subject.
I asked for a technical conversation and all I get is someone stating their opinion on why I shouldnt have fun and enjoy what I do in this hobby. But I suppose that there are those who would like to tell me what I can and cannot enjoy. Thank you very much. You are a real inspiration to amateur radio. Doug

If it will help, the same 6146 oscillator is shown in the 1959 handbook,
but there it has a smaller power supply, is described as a "Novice 50
watter", and has a somewhat-simpler PI output network instead of link
coupling. (I wonder if the later circuit was "downgraded" to reduce
the current through the crystal?)

>
>What razors and what pencils work best. And how much wire?

I built one of those as my first receiver, almost 40 years ago. Built many others over the years. Mine was copied from the kid's book, "All About Radio And Television". Never had a problem getting any of them to work.

The coil is wound on a toilet-tissue roll, with the paper removed. 120 turns of #26 enamel wire, close wound, was the book specification.

Detector used a plain (not blue) single edge razor blade. These are still available in hardware stores for use in cheap paint scrapers and such. Pencil lead was from a #2 pencil.

The neat part of the "All About" rx was the use of a bent-up safety pin to hold the pencil lead, which was held to the pin by wrapping a piece of #26 around both of them.

The real trick is having a good antenna and ground setup. For me it was the radiator pipe and the classic 70 feet of wire out the window to the crab apple tree.

Of course living less than 3 miles from WPEN on 950 AM sure helped.

I'd like to build a noise gate circuit for my HF receiver, to be located externally between the radio and antenna, but I'm not sure how to wind the toroids. The circuit I'm going to use (unless someone can suggest a better one for HF use) is at
http://www.lwca.org/library/articles/jtreed/gate/gate1b.htm

This uses two FT50-75 toroids and I understand I need to change these to FT50-43 for hf use (1.8- 30 Mhz). For 50 ohm input/ ouptut, how would I wind the toroids using 43's?

Thanks,
AJ

Hi everybody,

I am a bit perplex about your replies. This is why.

In the ARRL antenna book 17th edition, on page 24-16 (also in ARRL handbook 78th edition at page 19-5)you can see a diagram about loss in coaxial lines. At 150MHz, the matched attenuation of 100 ft of RG8 is just above 3 dB. Keep this figure in mind.

On the other hand, in the book of W2DU "Reflexions - Transmission Lines & Antennas" - 1st edition by ARRL, at page 1-5 you can see another diagram giving the additional loss caused by mismatch for various SWR (also at page 19-6 of ARRL handbook year 2001/ 78th edition). Imagine we have a SWR of 3. The diagram gives an additional loss of 1 dB due to mismatch for an attenuation of 3 dB in matched conditions. This is the consequence of the conjugate impedance theorem or the maximum transmitted power theorem. Total attenuation will thus be 4 dB instead of 3. (In the 80m band the match attenuation would be a bit less than 0.4 dB plus an additional loss of 0.2 dB for unmatched conditions (see also page 1-15 of W2DU book). Those figures could also be obtained from equations.

Is this small 1 dB additional loss at 150 MHz worth to climb at the top of the pole and the price of a remote controlled tuner ?

2384. Foolproof grid circuit for 4CX350 at 50MHz pse?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-19 18:55:47 UTC
From: Richard J <nospam@mah.se>
Message-ID: <amd6jg$st9$1@news.lth.se>
Source record: 41446

Hi group -

I ve seen many designs for the input of RF into the 4CX250 on 6m, but not so many for the 4CX350.
Currently, I am using a L-C-L input link that I find very sharp and also inefficient. It just doesn t work well - set it and forget it, you know....

I have a 25W rig with adjustable output, so I d settle for ,say, 5W input power.
The PA works at 1800V B+, 340V G2/screen, -70/25V G1/Bias.

Who amongst you has the ultimate design - easy to build, easy to adjust, stable and suitable?
Will it be a C-L, a LCL or a parallell LC network that comes out the winner?
Can I *please* have your coil data in millimeters, *please* ? :-)

Finally, space is an issue here - the grid compartment is small, really....

Tnx fer your pointers, time and help. 73 /Rick, SM7SCJ

AJ,

Don't be too disappointed if the thing doea not work. I built something like thi some years ago, got only marginal results on a good day. What I discovered was that:

1. The noise phase during positice AC cycles was not the same as during negative AC cycles.

2. There was sometimes more than one noise pulse during a half cycle of AC.

3. The phase of the noise jiggled back and fourth.

4. The noise "pulse"can be very wide; that is, it showed ringing

That 3 db loss is for a matched condition and no antenna tuner will be needed. If the swr of 3 is measured at the transmitter end and you have a 3 db loss in the transmssion line , look up how much of a mismatch you will have at the antenna. It is almost off the scale. The coax can be open and you will only measue a swr of about 3 with a 3 db loss in the line at 150 mhz. Then check out how much additional loss you get with a swr of 20 or greater that you will actually have at the antenna.

I would have to agree with you on all the above points. From my early homebrew experience, these circuits are great learning points and the original build usually metamorphasizes into a more advanced circuit (new oscillator, vfo, 7 bands, etc etc). My hats off to anyone who tackles homebrew projects at all in the hobby!

According to the same article in the 1956 handbook, L2 and L3 were made from a single piece of coil stock (Barker and Williamson type 3900 2" diameter, 8 turns/inch). The L2 section is 7 1/2 turns at one end of the assembly. L2 comprises the rest of the coil (32 turns), tapped at 16 turns for the 40 M tap.

2391. Re: Choosing receiver IF

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-19 22:54:21 UTC
From: Rob French <fulcrum99@earthlink.net>
Message-ID: <pan.2002.09.19.18.53.19.629378.2273@earthlink.net>
Source record: 41354

That was the main idea... that I would convert everything to a relatively high IF where I could just use one VCO, and then convert to I/Q from there... so no need for particularly narrow filtering at the IF.

Conceivably I could use direct conversion, with multiple VCO's to cover the tuning range. (I want to use DDS, but my understanding is that using a DDS directly for the LO in a receiver will result in too many spurs, so I was looking at a PLL-"cleaned" DDS).

Source record: 41355

I seem to recall reading (I don't have my books with me at this TDY unfortunately) some discussion of how the LO signal to a mixer should ideally be a square wave. Is this true for all mixers? As I understand it, this has to do with the switching function of the mixer. If this is the case, I was wondering why not remove the spurs issue of a DDS by converting it to a square wave to drive the mixer. Or am I missing something significant here...

Thank you Ralph for your reply. About the exemple, I haven't see yet in those books if the SWR is supposed to be mesured at the antenna or at the transmitter end. I think I will put this example in a Smith' diagram just for seing what will happen. Anyway an SWR of 20 at the antenna is not realistic because it would require first some adjustment at the aerial. So my assumption of a SWR of 3 or even 5 could be reasonably good and in this case the books are right.

The crystal current would probably break the current style crystals. The old
ft243 style could handle a little more current and the still older and bigger
crystals
would probably handle the current OK.

If the spurs have a phase modulation component (as most spurs from a DDS do)
converting to a square wave will not help.

It won't really be that bad. Use a high-quality DDS chip like an
AD9852/AD9854, and your LO spurs will be down around -80 dBc. Not
great, but an embarrassing number of ham and commercial rigs have
shipped with worse performance than that.

I'd say get the basic system up and running with an AD9852/9854, and if
you have spurious-response problems, deal with it then.

I wonder if for the RX a regenerative design might have some
advantages over the direct conversion approach -- more gain?
I'd also think it would be possible to have the regenerative RX
revert to an xtal controlled oscillator for transmission, or even
as a VFO.

You can. The AD9852/9854 DDS chips, and probably others as well, have a
built-in comparator just for that purpose.

The Mini-Circuits mixer app notes encourage the use of square-wave drive
when possible.

2400. Re: square- versus sine-wave LO to mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-20 00:22:14 UTC
From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <amdpno$j6h$1@slb3.atl.mindspring.net>
Source record: 41363

In most cases, spurs and noise from the DDS LO in mixer applications are phase types of signals.... Converting to a square wave can't change that.

It can improve amplitude noise from an LO, but this is usually not the problem in modern DDS synthesizers. The older generation VFO type LO usually was also fine in this regard. Once an LO drive saturates the mixer, amplitude noise on the LO drive is much less likely to occur and any decent LO design provides enough output drive.

==========

However, a square wave into the mixer can improve strong signal handing ability by transiting THROUGH the zero crossing point quickly and that zero crossing point in the LO drive is where the mixer is most prone to intermod.

This doesn't alter the spurs a DDS generates, but it does improve the third order intermod to some degree.

I've sometimes thought it might be possible to key a regen circuit into
full osc. for xmit use.
But, the best way to attempt that would be using a xistor as some
sort of a switch -- thereby doubling the xistor count here. :-)
But, you gotta know, you'll play hell with freq shift between
rcv and xmit -- and there'd be chirps, for sure.

Would slipping in a tunnel diode be cheating?

You are right about the crystal current breaking the crystal. With the
6146 oscillator even the
FT243 crystals will get very hot and can break with all the drive on
them. You have to be
careful and keep the crystal drive in check.

Thanks to everyone who responded to this. I did end up finding the culprit and it was a loose solder joint on a capacitor in the amp section. Unfortunately, it was pointed out to me that the amp heating up is also really an issue, and I should adjust the bias.

I was able to adjust the 'good' channel fine. Unfortunately on the bad channel, adjusting the variable resistor allows me to go only as low as 400mv where a 50mv is desired (this measurement is across two resistors between the opposing power transistors... one supplying + and one -).

I guess at this point, I can only assume that one of the diodes, caps or smaller transistors in that circuit is bad. The power transistors seem OK, since both pairs are behaving the same, and I believe that all the connections and resistors are fine. . I think I may be beyond my testing abilities at this point... any further recommendations? I did spray things with freeze spray with no effect.

Thanks again.
(what would you expect a shop to charge to fix something like that?)
Gregg Horan

So I attempted to set the bias

Another cure for single reflection problems is circular polarisation.
Even a short helix will provide good rejection.

There's a chart in the ARRL Antenna Book that indicates for an SWR of 3:1
at the transmitter and 3dB matched line loss, the SWR at the antenna is
about 75:1. Fig 25, page 16-15, 17th edition, 1993.

Huh? If you've got only one transistor, you don't have much leeway.
Ian's comment was more interesting to me than the concept of making
a one-transistor transceiver.

You want to try things, yet you're looking for suggestions on how
to make your one-transistor transceiver receive better. If the
challenge is in doing it, then you should be the one telling
us how to do it, rather than griping about our comments about
how the fewest parts may not make for simplest construction or decent
performance.

Side issues are always important, because the fastest way between
two points may not be the most direct route.

You're set in a mindset of a "direct conversion' receiver, ie
an oscillator and mixer. So you're trying to get an oscillator
to also act as a mixer, rather than exploring other concepts.

In the beginning, or more or less, there was the regen receiver.
It was a big step beyond the coherers and cat-whisker detectors
that were pretty much the norm up to that point. When oscillating,
it isn't all that different from the concept of direct conversion.

But when Armstrong came across regeneration, he also came
across a means of electronically generating a signal. Look up
the Armstrong oscillator. Look up regen receivers, and all the comments
about how the signal they generated would often/sometimes interfere
with the neighbors reception.

So start with trying to make a good receiver, and then do whatever
it takes to radiate a signal, rather than starting with a signal

source and trying to also use it as a mixer.

It's all been done, long ago. The issues of coupling to the antenna. The problems of blocking from strong signals, and the detector going out of regeneration when the antenna waved in the wind. There were quirks and there were problems, but people lived with them.

(One of Armstrong's other inventions, the superregenerative receiver, showed up in a lot of simple transceivers, where the same active element was used on both transmit and receive. Though I'm not sure how much was a simple change of something to go from receive to transmit and how much of it was outright switching the whole tube or transistor to the other circuit.)

Then when you've got a good one-transistor receiver, then go on and see how to get power out of it into the antenna. Since you've already got an oscillator (since a regen is an oscillator with controllable feedback or to look at it another way, an amplifier with controllable feedback), the issues are whether it will be stable enough, with a varying load, and whether you can get enough power out of it to be half-way useable.

Look up Charles Kitchin's articles in Communications Quarterly, Electronics Now, and QST. He's gone back and looked at the regen receiver, examining it's benefits and faults, and then has created various designs using solid-state components. Usually, they are relatively simple, but he has taken the path that a few extra components are worthwhile if they will improve operation. So instead of the one-tube receiver of the 1920's, built with as few components as possible, he may throw in a voltage regulator, and be using a decent oscillator design (and mechanically built it like an oscillator). He's made a point of understanding the regen, and going right back to the beginning, so he can make an attempt at improving on things. This is a far cry from the regens of the past forty years, where someone picked a tube circuit, put in a transistor or FET instead of the tube, and lived with the imperfections.

Charles Kitchin even wrote about a crystal controlled regen receiver, for listening to W1AW code practice runs. Of course, he cheats and uses an external diode detector, so in some ways it's on the verge of being less regen and more "direct conversion" as we know it. But it would give you a stable oscillator for the sending part, which would take a lot more effort if you started with an LC oscillator. This was in QST, sometime in the past ten years, though I don't recall the exact date.

One additional thing to remember is that wire dipoles (which are frequently used on HF with a tuner) have a quite simple radiation pattern and hence, the gain is quite low. Operating the antenna slightly off resonance (with a tuner) does not radically alter the radiation pattern or gain.

However, yagis with a large number of parasitic elements (as usually used on VHF/UHF) heavily depends on the various resonance frequencies of the various parasitic elements. Even if you operate the radiating element (with a tuner) slightly off the design frequency, all the parasitic elements are still operating at the original design frequency, thus the radiation pattern will quickly deteriorate when operating away from the design frequency. Since antenna gain is simply the ability to concentrate power to the desired direction (and multiplied by the antenna efficiency), the gain will also drop outside the design frequency. In the worst case, trying to use an antenna tuner (even at the antenna) with its internal losses will reduce the antenna efficiency and also reduce the true gain of the antenna even further.

Thus, this is an additional reason why antenna tuners are not used on VHF/UHF.

>ideally be a square wave. Is this true for all mixers? As I understand
>it, this has to do with the switching function of the mixer.

This is true for a switching type mixers. However, such mixers also
produce mixing products with the harmonics of the LO drive. Thus, the
receiver will have strong spurious responses at 3*fLO +/- fIF and
5*fLO +/- fIF so that these frequencies must be prevented from
reaching the mixer by using sufficient front end selectivity.

With a high IF and the LO in the VHF, this is not usually an issue,
however front end filters designed for HF use might have quite high
parasitic inductances and capacitances, which may let VHF/UHF signals
through or the VHF/UHF signal may be directly coupled to a badly
shielded mixer, thus strong FM BC and TV signals could end up in the
IF.

However, if you can find an ideal four quadrant analog multiplier, you
could use a clean sine wave as the LO drive and directly use the
trigonometric relationship sin(fRF)*sin(fLO) = 0.5*(cos(fRF-fLO) -
cos(fRF+fLO)) , which does not have the spurious responses at the odd
harmonics of the LO. The problem is finding an ideal 4Q multiplier:-),
so it easier to approximate this with a switching mixer and a square
wave LO.

>If this is
>the case, I was wondering why not remove the spurs issue of a DDS by
>converting it to a square wave to drive the mixer. Or am I missing
>something significant here...

The problem is timing jitter (due to sampling and quantisation) which
can also viewed as phase noise, which can not be removed by running it
through an amplitude limiter.

Hi Jose,

You will notice from the other responses, that many consider your request odd. There is little that readily translates from the discrete tuning elements of HF to VHF/UHF; and you would probably find the standard tuner of these bands more appropriate: the single or double stub tuner.

Laboratory models are coaxial, with variable length out to ï¿½ meter. You don't need to have much more variability than that, but you do need some freedom to move it (with a T connection) in relation to the load. This is the major difficulty with a single stub tuner being applied to a wide variety of loads. When you expect to encounter this variety, then double stub tuners (or simply two single stub tuners, separated by an arbitrary distance) are preferred.

Hi Terry,

As others in this thread have mentioned, sometimes all that is needed is a good cleaning. If however the carbon coating is worn off the silicon rubber keypad, I use this method with good results. Wash your hands to remove any oils. Cut small pieces of aluminum foil to the proper size (a little larger than the pad) with an exacto knife or small scissors. Place a very small drop of 3M Plastic Emblem and Trim Adhesive on a piece of paper or cardboard. Pick up an even smaller amount from the drop of adhesive with a toothpick. Touch the sticky end of the toothpick to a piece of foil. The foil will stick to the toothpick. Place the toothpick with foil on the surface to be repaired toothpick down. With your oil free finger, push down on the foil to hold it in place and pull out the toothpick. It may take several tries to get the hang of it. The adhesive sets in about a minute and you may not get more than one or two foil pieces done before you need a fresh drop. If you get too much adhesive on the toothpick, it smushes around the edges of the foil and sticks the foil to your finger. The 3M adhesive sticks well enough to do the job but stays flexible enough to remove later without damage. I have an old big dish satellite receiver with RF remotes (3) that I can't live without. It keeps them working.

Regards,
Ron

Hi dear CAM,

We are not speaking about the same things. I never told about a SWR of 3 at the transmitter end of the line in the conditions of attenuation you described. I only told that if Jose Luis (as told in his original message) needs an antenna tuner, why putting it at the antenna end. It is common sense, if he has a very bad SWR at the aerial, he must first cure the problem at his antenna. In this case, my assumption of starting with a SWR of about 3 AT THE ANTENNA is quite reasonable. The rest is obvious and corresponds to my previous posts.

BTW I never found the chart you mentionned at the page / chapter / edition / book, indicated in your last message. Can you check and repost the reference. Thank you.

Source record: 41381

It's easy. Firstly build a one transistor xtal osc/tx using a 2N2222. Then build a regen receiver also using a 2N2222. Then take out both transistors, solder one transistor to the back of a three pole two position switch (TX/RX) and wire it so you switch between the two. If the emitter is a common earth, you could possibly get away with a DPDT switch.

The rx sensitivity & recovered audio would be way down, you'd have no way of netting, and your tx power would be very low and you'd be rockbound so your contacts would be few, far between (and probably prearranged), but if you like building more than operating, go for it!

But beginners seeking a practical QRP transceiver that will get you worthwhile contacts that are a pleasure rather than a chore should look elsewhere.

Source record: 41380

I am using a 3.560 MHz crystal in my one-valve TX see http://www.hanssummers.com/radio/cwtx/index.htm. It's in a standard HC49 case and can get a little hot if the circuit isn't tuned well. This TX puts out about 10W on 80m. A variable capacitor pulls the frequency +/- 250 Hz which gives some flexibility.

Talking of how hard it is with calling CQ when rockbound: I have a short bit of bent wire in the attic, which my homebrewed ATU (http://www.hanssummers.com/radio/atu/atu.htm) manages to tune to 1.1:1 on 80m. I have a homebrew RX see http://www.hanssummers.com/radio/polyphase/index.htm. With this setup I don't find CQ'ing a problem, I get answers over 50% of the time and the quite a lot of the remaining unanswered CQ'ing is due to me being overoptimistic at the wrong times. On 80m in the UK I find it Ok between sunset and about 2200 UTC. I had 35 QSO's with this rig mostly UK (G, GM, GW, 2E, M, MM, MX) but also Europe (SM, PA, F, DL & DK).

Often finding disturbing QRM on 80m I want to add an extra crystal or two, in particular for 3.558 MHz. I am going to attempt a method of "homebrewing" your own crystal frequencies: apparently if you take the case off a nearby (higher) frequency e.g. the popular TV crystal 3.579545MHz and draw on the crystal surface with an indelible felt tip marker pen the weight of the ink lowers the frequency somewhat. With care it is said to be possible to get 40 KHz off the official crystal frequency without degrading crystal performance.

Hallo everybody,
I'm looking for someone using B&W AP-10A antenna,
short and telescopic HF mobile antenna.
I'd like to know more about the A verison...
I'm using now the 5 coils version... it's quite boring.

bye for now

I have for sale 1 full size "HY-Gain" beam 10 meters. fully assembled
for your inspection. 13' Boom and longest element is 22' $75.00 I also
have a steel tower totaling 25'. this is in 3 sections 1 10 foot st8 and 1
5foot st8 and 1 10 foot top section. I don't not have a rotator. $50.00.
pickup only from Nashua,NewHampshire. I am selling these because they are to
big for my new QTH. This beam has spent a large portion of its life in
storage. 73's Jeff AA1GR

A ham I know tested the loss at 2 meters through 100 feet of cheap RG8X
coax into a dummy load. Driving the input with 45 watts he found the
wattmeter at the load end measured 5 watts.
That was into a MATCHED load, 1:1 with nothing reflected.

To clarify - the phase spurs are due to variations in the timing of the transitions of the square wave. If the jitter is random you get phase noise, if it is coherent (ie regular) then you will get spurs.

Don't worry, you're not alone! I checked on the same 17th edition and only
found a 'drilling template for...'.
But I found my 17th edition is a second print of '94.
Fantastic! I suppose the first print of '94 is something different too!

2426. Re: single transistor transciever

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-20 15:43:57 UTC
From: mcalhoun@ksu.edu
Message-ID: <amffnt$80a@unix2.cc.ksu.edu>
Source record: 41388

>It's easy. Firstly build a one transistor xtal osc/tx using a 2N2222. Then
>....[snip]....

Although I don't recall ever seeing a one-transistor transceiver in the literature, the September, 1945, issue of QST described a one (if you don't count the rectifier!) TUBE transceiver; a dual triode serving as a regenerative receiver and a simple crystal oscillator, respectively.

A British QRP club's bulletin (SPRAT? I have no citation, just a torn-out page 20) once described RV3GM's "Micro-80", in which the TOTAL part count beyond the obvious crystal, key, phones, antenna, ground, and power supply was only 19! (4 transistors: a crystal osc., a power amplifier/mixer, and a Darlington pair as an audio amplifier), 1 tapped inductor, 1 RF choke, 5 resistors, 8 capacitors! Someday I want to build one just to see how it works!

The November, 1990, issue of "73 Amateur Radio Today" described WB0NQM's "TTL Transceiver for 40 Meters" which used three IC's (a 74LS00N xtal oscillator, a 74LS03N amplifier, and an LM386 audio amplifier, with two diodes acting as detector/mixer, if I read the schematic correctly).

Finally (at least in my article collection) was G4ADJ's November, 1975, "Ham Radio" article "Using TTL ICs in single-sideband equipment" which showed a complete SSB transceiver using only three SN7400 NAND IC's! Since each 7400 has four two-input gates, there were 12 active devices, and they were used as:
2 in a crystal oscillator
2 as oscillator buffers (one each for xmtr and rcvr)
2 as control gates (one each for xmtr and rcvr)
2 in the PTT circuit (one each for xmtr and rcvr)
1 modulator
1 clipper/amplifier
1 RF amplifier
1 demodulator
There were a few resistors and capacitors spread around, the power output was only about 10 mW PEP, and receiver sensitivity was only about 50 mV, but "Hey!", what do you expect with so few parts? Just add a preselector with some gain....

Source record: 41389

If the mixer is a passive one with transformers, then
the trouble with trying to drive it with a square wave
is that the square wave tends to get distorted passing
through the transformers. OTOH, a sine wave will not
get distorted by a transformer. Another problem with
square wave excitation is that the square wave you generate
must have exactly 50% duty cycle for optimum performance
of the mixer. This requires using balanced drive circuits and
is non-trivial. With a sine wave, you merely filter out the
harmonics with a low pass filter to guarantee 50% duty cycle.

Hey Mark,

Thanks for the response. I definately haven't been using the reciever
since I noted how hot it ran and the bad bias.

I checked the voltage across this diode (actually I think it is a
varistor... or am I checking the wrong thing?) With the reciever
powered off, my multimeter's diode tester (manual says .5mA @ .6V),
the good channel reads 1.28V, while the bad channel reads 0.73V. An
ohmmeter across both reads the same (12Mohms). These readings are
with them still soldered to the board... dunno if secondary circuits
are affecting that reading.

The varistor is has the number '50' on it, with a tiny tan dot also.
Labeled STV4H in the manual. I can't seem to find any references
anywhere to figure out what to replace that with if it is even the
problem.

Thanks again for your input.

I don't have much experience with such units but recently had a problem with an 70s vintage Sansui 8080 DB receiver of mine.
Three major things I noted....
1. Many small electrolytics were on the verge of being officially bad. I replaced the worst of the lot in the AF/PS sections with a mind to go back sometime and do them all.
2. All of one certain value/type of resistor had drifted way off value. Others seemed to be fine but exery example of that particular type was bad in varying degrees.
3. The solder in this Sansui is horrible. It is like it has dry rotted anywhere there is heat nearby. For instance, I thought all of my dial lamps were burnt out but it was bad solder on every joint. I found my main problem on the PS board where one end of a large resistor had 'jumped' completely off the output protection board since the solder no longer held it. It had overheated due to a bad resistor in #2.

Any of the above can result in weird/noisy operation.

Hope this helps.

Rick, I sense a rather thin argument here. While I don't disagree with what you claim, I do want to point out that some mixer transformers are better than others. If you choose with care, you may find that you can pass many octaves of harmonic energy through the mixer transformers with very little distortion.

Second, although I agree that group delay through the transformer can distort a square wave, I think it's a secondary effect at best. After all, the goal is to driving a mixer diode or JFET in to saturation or cut-off. The differences, if there are any to be measured, must be pretty small.

I would be very curious if anyone has a real-world comparison example of what happens in each case. I'll be surprised if there is more than a 1 dB of performance difference in spurious products.

I have experienced VHF feed-through in a receiver using a diode mixer. The effect was that FM BC signals would mix with the firfth harmonic of the LO and end up in the IF. In that case the receiver seemed to be sensitive to direct coupling to the circuit in the vicinity of the mixer. Does anyone have any experiene for when a mixer is badly shielded as opposed to well shielded?

OK, let's work backwards. If the SWR at the antenna is 3:1 and the loss in
the coax is 3dB, the SWR at the transmitter is less than 2:1 and there is
no need for an antenna tuner.

If the losses due to SWR in the coax feedline at vhf/uhf are not enough to
worry about, then the impedance seen by the transmitter is probably not far
enough away from 50 ohms to require an antenna tuner. This is one thing that
makes vhf/uhf somewhat different from HF.

Wow, that was cheap RG8x. The wireman says the loss in RG8x on 2m
should be about 4.5dB. Your buddy's loss was about 9.5dB.

I was looking at two publications. I might have gotten them mixed up.
The ARRL Antenna Book, 15th edition, page 24-13, Fig. 18 and
The ARRL Handbook, 17th edition, page 16-15, Fig. 25
Sorry if I got them mixed up.

Hi,
I'm trying to repair a pulse generator which for now only oscillates at
10 MHz. I've verified that the spikes which trigger the pulses are correctly
made when I vary the frequency knob but I've also discovered a 500 mV
peak to peak 10 MHz oscillation. As I trace the signal down further, the
spikes die away and the generator ends up triggering on these
oscillations. The whole problematic section is composed of transistors and
includes a Schmitt trigger. Any ideas on how to find the troublemaker if
my diagnosis is right?
Thanks,
Gabriel

2442. Parts needed for Heathkit DC power supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-20 22:57:52 UTC
From: aa8wl <aa8wl@comcast.net>
Message-ID: <3D8BA7B1.C1528AB3@comcast.net>
Source record: 41305

I would like to locate (5) capacitors for an older Heathkit DC power supply I just bought. It is the HP-13 and I opened the case and one of the capacitors had a hole in the end and material coming out of the hole. I have never seen anything like this happen before so I have decided to replace all (5) Five at the same time. The Heathkit part number is: 25-207 and they are 20 ufd @ 500V electrolytic . I would like to find some at the original cost 85 cents each (hi hi) but with inflation I would expect them to be somewhat higher these days. Also, if you might have an old unit for parts I would be interested. Thanks in advance, 73' de aa8wl Sam

I use my flatbed scanner, and Adobe PhotoShop Le, takes a little trial and error, but it works nice.
Remove the meter scale, and scan it, then work it over in your image editing software, then save it at a high dpi rate like 600-1200dpi, and print it on your inkjet or laser printer. Sizing it correctly will take a few tries.

The SWR is usually the ratio of the transmission line and antenna. Unless using part of the transmission line to match the antenna, then the swr should be measured at the antenna. I ahve seen where sometimes a 1/4 wavelenght 70 ohm coax will be used right at the antenna to match the antenna to a 50 ohm line. Also a 50 ohm 1/4 wavelength will be used to match to a 70 ohm trannsmission line. Then the swr will be measured at the end of the 1/4 wavelength matching section that is actually part of the antenna system and not the transmission line. I hope that comes out the way I ment it to.

Most people measuer the swr at the transmitter because it is easy to get to and also it should be checked there to be sure the transmitter is loading into the usually 50 ohm load it is designed for. If the coax loss is low as at 40 meters and below it does not make much differance as the swr at either end will be close to the same provided the lenght is not near a 1/4 wavelenght or other multiple that turns the line into a 'matching segment'. As the losses go up in the coax the swr measured at the transmitter will seem to be lower. You can take about 300 feet (probably less but I did it at this length) of rg-58 and leave one end open at two meters and see almost a perfect 1:1 swr when it should be infiniate.

>If the losses due to SWR in the coax feedline at vhf/uhf are not enough to worry about, then the impedance seen by the transmitter is probably not far
enough away from 50 ohms to require an antenna tuner. This is one thing that
makes vhf/uhf somewhat different from HF.

I do agree 100%. Even an OM replied me privately a few days ago and we arrived at the conclusion that an antenna tuner is not necessary. And he added:

> A tuner for 2M would, I think, have to face some rather nasty design tradeoffs. You'd probably need to use physically-small components, to keep the tuner's parasitics under control... but such small components would be very limited in the amount of loss energy they could dissipate. If you try pushing 50 watts through small inductors and trimmer caps, in a tuner with 5-10% losses (not unusual for a tuner) you'll probably fry the inductors.

Well. I think you need to open it up from the circuit and test it. These usually go open, not leaky, which is what your reading would indicate. There may be something nearby shorted or leaky. If the STV4H is really bad, you can probably find one or rig a diode stack in it's place. Stay in touch. We can probably get you through this.

Rethinking, it may have been a bit more than 100 feet. But it was that
cheapie silver jacketed stuff that was the rage for awhile. I checked
some of it once for braid coverage and you could see lots of center
insulation through it. Sure wasn't usable on 2 meters except for very
short runs.

And the boss didn't want to believe me when I told him there was a
defective DB24 antenna on the other end of that 265 foot run of one and
a half inch hard line up on the tower with an SWR of less than 2:1! The
transmitter couldn't be heard out of town where it normally worked over
a hundred miles at 155mHz.
(Installation of a new DB24 took care of the problem. Old one had lost a
couple of weather seals and was waterlogged)

That was kind of a bizarre scheme, though it did qualify as trying
new things.

He was linearizing the TTL gates either by feedback resistors or
by biasing the inputs. That gave him his active elements. But he
didn't come up with a balanced modulator, so he just used a TTL
gate as a regular AM modulator, and the crystal filter was supposed
to strip out not only the opposite sideband, but the carrier.

Memory tells me it was just an IF strip, and that unless you were
willing to build a crystal filter on the desired signal frequency,
you'd need a pair of mixers and an oscillator to make it useful.

By that time CMOS was well around, though it had more speed
limitations than the straight TTL. If you could accept putting
it in the 455KHz or so range, one could have gone to CMOS,
and used cmos switches for the balanced modulator and product
detector.

Most of the stores you're looking for dried up and blew away a long time
ago. However, last I knew, Marvac Electronics in the Walnut Center (east of
Patterson/Hollister Ave. intersection) was still in business.
The only other one I know of is in Santa Maria.

Can anyone help me out with any information about the coil data of L2
and L3
in this schematic
it from ARRL 1957 Handbook

Thanks in advance
--
http://deosiereas.virtualave.net

From the '57 Handbook, pp 173-174:

"Standard coil stock (B&W 3900, 2-inch diam., 8 turns per inch, No. 14 wire) is used for L2L3. A total of 38 turns is cut from the original stock. At one end of the piece, a single turn is unwound from the support bars. From this end, count up 7 1/2 turns and cut the seventh turn. The cut should be made at the support bar opposite the bar from which the first lead extends. The leads from the cut point are separated from the side support bars and brought around to the same bar as the first lead. At the other end of the coil, which will be the top, a lead is unwound from the support bar and extended from the bar opposite the one with the three leans. This coil is shown in one of the photographs.
Counting from the top, the 15th and 17th turns are bent in, allowing access to the 16th turn. This is for the 40-meter tap. A four-inch length of wire can be soldered to this point. The other end should be connected to the switch terminal on S4."

The photograph referred to is Fig. 6-41, "Close-up view of the coil construction.", on page 175. The schematic chows that this is a link-coupled circuit, and the point of all the written directions is to use one piece of B&W coil stock as both the tapped primary and as the secondary, separating the two by removing one turn of wire. Using one piece of B&W stock for both the primary and the secondary, which in the photograph is shown mounted vertically on ceramic insulators via lugs soldered to the secondary, makes for a clean, compact and mechanically-stable package.

Nominally speaking, a pulse generator does not oscillate.
I would suggest that you get a schematic or make one, so you have
something to follow.
Look at the method of generating the pulse: (1) dump energy into a
delay line (which determines max width) and another switch turns it off;
(2) turn on and then of the output driver, (3) ??.
Start at the beginning and go stage by stage; look for bad capacitors,
burnt or cracked resistors, bad transistors.
Try to figure out if something else went bad and that part was thereby
destroyed so the cause gets fixed, not the symptom (ie: do *not* work
like a doctor).

I've been following the thread and one thing is troubling me. The concept
of a one device transceiver is probably acheivable, but very difficult to
pull off. It is really a project for those of us with the experience and
patience which takes years to develope. I would hate to know that we gave
some new kid, who was eager to get on the air, the idea that it was a
piece of cake and then have him fail. The experiencd person would, number
one recognize when there was a problem and then, number two, would have
the patience and experience to correct it. I remember when I was starting,
that I bearly know what a rectifier was and relied on "Electronics
Illustrated" and other mags to give me guidance. I know that the
alternative is to guide them into more complicated circuits, but with a
little explaination as to the why's, at least when their project is done,
it'll work to a point where they will be encouraged to go beyond that
rather than hang their head down in disappointment. My first project had a
$2.00 electrolytic that I bought from Allied after saving four weeks for
it, which caught fire when my circuit was turned on. It wasn't fun.

Electronics should be and is fun. Let's keep it that way.

My $0.02.

Happy Trails,

Steve WB4CZR

>

All this reminds me of an early troubleshooting experience. While
assigned to the educational TV station at the U S Army Signal School at
Fort Monmouth, NJ about 40 years ago, I was a videotape technician
working on one of the early videotape machines, which bore not even a
vague resemblence to anything seen today.
It consisted of three 6 foot racks of equipment in slide-out drawers
with an open tape transport deck that used 2 inch magnetic tape running
through a large open headwheel assembly. It was monochrome, of course,
all solid state, but IC's were still in the future, and all circuitry
was of discrete components.
One day suddenly the monitor displayed a horizontal black stripe across
the middle of the screen that stayed there. Tracing the flow to a
particular board, I unlocked that drawer and pulled it out, intending to
troubleshoot with a scope. In short order the trouble disappeared. When
the drawer was replaced into the rack, it would reappear. The relatively
small temperature change between the rack air and room air would heal
the fault!
How to find the defective component? I used a desk lamp with a 60 watt
bulb, and a file card. Holding the lamp close to the extended circuit
board would heat it up and quickly introduce the fault. Using the file

card, I covered each diode on the board in turn, shielding it from the lamp's heat, and when I covered the the third diode, the fault disappeared. Removing the card would bring it back. So I Changed out that diode and viola, no more problem.

Not exactly high tech, but quick and effective. The whole repair took less than 15 minutes.

Dick

> Nominally speaking, a pulse generator does not oscillate.

Sure they do (or can). An astable multivibrator is nothing but an oscillator, and a Schmitt trigger is a variation on the monostable multivibrator design. In all cases, very high gain is employed in order to drive the transistors into saturation -- to make them go to one and only one state, rather than to amplify their input current.

When one of the circuit components drifts, or when one of the transistors starts to fail, it is common for the high gain to be lost, and for oscillations to set in via the feedback mechanism which is already present. There is no longer complete saturation of one of the stages, and that allows some conventional amplification to take place.

Usually, the designer adds additional circuitry intended to suppress such oscillations, but it may not be present in simpler equipment. In any case, the old tried and true methods will apply.

Check out the passive components (resistors, inductors, capacitors) first, and see if one of them has drifted or failed with time. If you have a voltage chart (as in a Sam's Photofact schematic), start with a check for correct operating voltages at the various solder points. You can also try "freezing" various components by means of a special spray can you can purchase. Sometimes, lowering the temperature of a resistor or a capacitor will reveal the problem part.

In these days of printed circuit boards and VLSI, it is common to swap out the board rather than to test components, but it looks as though the old methods will be needed here instead. I'll bet that a passive

component has changed value, or that a solder joint is bad. (I'd suspect the transistors last.)

2466. New DATEK VFO kit- Any experience?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-21 14:25:37 UTC
From: Dick Carroll <dixie@townsqr.com>
Message-ID: <amhvh1$re2$0@208.206.142.71>
Source record: 41329

New direction for this thread...

The new issue of Worldradio Magazine (Oct '02) page 59 shows a new VFO kit from Datek (<www.philmore-datek.com> click on new products, look for part number 80-1410) that is said to eliminate virtually thousands of crystals. Frequency change is made by changing resistance, using a potentiometer. Suggested price is $15.99.

Blurb: "This new Basic VFO is intended to be used in place of crystals in transmitter and receiver circuits.....will provide a low cost precision oscillator that could be used as a switching power supply clock reference, in addition to use as a fixed crystal oscillator replacement.....can be assembled in about 20 minutes and is supplied with parts for using the circuit in the 40 meter band. It will tune from approximately 6.9 to 7.2 MHz as supplied. Instructions are supplied on how to swap out a resistor and capacitor making the circuit usable from 100 kHz to 33Mhz. Also included is a circuit schematic for a 40 meter 5 watt transmitter than can be used with the VFO circuit. It will operate on any DC voltage from six to fourteen volts and draws approximately 140mA.....it employs the new LTC1799 IC."

If this thing is anywhere near as good as advertised, it will surely be a great aid homebrewers. Coming up with a simple, cheap, stable quality VFO has always been problematical.

Further reading on the quoted website indicates this unit supplies square wave output. That looks to me like a potential problem for use in the radio applications noted, without some "cleanup" circuitry following.

Any out there with experience in this area care to comment?

I have a crystal controlled Motorola 2-20 mHz HF transceiver for which I would like to adapt one of these units to substitute for the crystals. This would entail creating three VFO frequency ranges. If the square wave output will cause lots of spurs and birdies, it wouldn't be worth the effort - I don't want to put RF trash on the air. I need input from someone with experience in this area before deciding how to proceed as I have no experience with using square waves in RF. Of course it's done extensively in factory built rigs these days.
Thanks.

I read in sci.electronics.design that Boris Pinson <Boris@bed-
wetter.com> wrote (in <3D8C206B.9AA03111@bed-wetter.com>) about
'spurious oscillations', on Sat, 21 Sep 2002:
>(I'd
>suspect the transistors last.)

Indeed. Unless any of them (diodes and zeners as well) has gold-plated
leads. These give rise to high-resistance joints between the lead wire
and the plating, which can be a right PITA to find.

If Motorola made is specifically for Radio Shack/Tandy, your
chances of getting service data on it from anyone but RS/T are slim at
best. Motorola takes their contract manufacturing -very- seriously. I
know this from having spent 7 years with them back when there were
company-owned service centers and a Comm Sector. Heck, we were the
company shops and not even we could get service data on some units!

My advice, if you want to put up a repeater, would simply be to
hunt around at hamfests or on E-pay. Anything from an old Motran repeater
on up to an MSF5000 would probably do just fine.

Can't help you on the pagers. No service manual for them.

Good hunting.

From: Rob French <fulcrum99@earthlink.net>
Message-ID: <pan.2002.09.21.13.04.43.451934.22987@earthlink.net>
Source record: 41338

Correct me if I'm wrong here. As I understand it, I can generate quadrature signals from RF in one of two ways.

A) Split the incoming RF and feed it to two different mixers. The mixers are fed with the same LO frequency, but 90 degrees out of phase.

B) Split the incoming RF and feed it to two different mixers, but shift the RF input to one mixer by 90 degrees. The mixers each get the same LO frequency, with no phase shift.

If I am correct, my next question is, which is typically easier to do well? Assuming this is used at the backside of an IF (rather than a wideband RF), I'll have a constant IF frequency and a constant LO frequency, so in either case, the phase shift doesn't have to be wideband. My thought, though, is that I can probably make a more consistent 90 degree shifted LO signal from a crystal osc divided a couple of times and shifted using some flip-flops.

Thoughts?

-Rob

Your idea with the LO seems to be the more viable. Shifting 90 degrees in the analog sense is not easily achieved. Even so, it doesn't have to be perfect to get good results either way.

Happy Trails and Experimentation,

I found an old 20's homebrew radio in grandpa's attic and would like some hook up information. I've read a number of books and have tried to apply the information to this unit. Before it's juiced up I'd like to be sure I don't fry anything.

A wiring diagram and a couple of questions can be found at:
http://www.bmara.com/radio.htm

reply via this newsgroup or e-mail..... rfred45@charter.net

If you could help me out it will surly be appreciated..Thanks

Hello!

Are you trying to generate a single sideband signal or a image free converter? In both cases, the LO signal and the other signal (IF or Audio) must both have 90 degrees shift.
As you mention 90 degrees shift for the LO is easily obtained from FF dividers. In fact many converters IC's use this technology up to 2.5 Ghz (Maxim). 90 degrees can also be obtained for the LO of each mixer by splitting with a 3 db quadrature coupler (or splitter). Jos!

Hi!
You did not state which frequency you are looking for! Look at DIGI-KEY catalog.
They have a line or two of programmable crystal oscillators up to 130 Mhz with stability of plus/minus 25 PPM over a wide temp. range in DIP and other packages! They cost less than a single crystal manufactured to your frequency. Their device can be programmed twice. You just give the frequency over the phone and you get your oscillator the next day in north America!

Regards! Jos

Check DigiKey and Mouser catalogs for small unit quantities. Also surplus sellers like MECI, Hosfelt, BG Micro etc., sometimes have limited quantities of certain models.

Computer applications don't call for a lot of frequency stability,
Try to get one with smallest ppm/ degree for less temp drift.
The frequency tolerence in parts per million (PPM) is published for the models in the DigiKey and Mouser catalogs. Usually not to good for VHF or UHF applications.

Another problem is that most models don't have a tuning adjustment, although the pricier ones have a voltage controlled tuning lead. Without a means to tune them they can start off many ppm from where you want them.

Most have TTL output square wave so you need to filter the harmonics.

Hope this helps.

Hi!

Plessey used to have a good mixer for this purpose; (SL.......)
Unfortunately, it has been discontinued. But Analog Devices came out with the
500 Mhz AD831 Mixer which is very efficient in designs similar to yours; the
output frequency range is 250 Mhz so there is no problem with high frequency
IF. Jos!

The programmables are reportedly "dirtier" than the standard ones so might not be good for RF projects.

The pageboy II has no squelch circuit if it is tone and voice. The audio is on if the decoder opens the audio amp. 5-10 minutes and your battery would probably be dead. If they are not tone and voice but tone only, there is no audio section, just an oscillator and a transducer for generating the beep. Look for the Minitor series, as these are monitor receivers with audio and squelch systems. Director series has audio sections but no squelch circuit, so use as a monitor receiver is limited. They can be converted to be like a minitor, but somewhat costly to do.

I don't think Radio Shack ever made radios for Motorola, I believe it is the other way around. If that is the case, check the Motorola model number (or type acceptance number) and run it thru the compliance database at the FCC to see what it really is. Motorola Parts ID may be able to tell you what it is, or a Motorola Service Shop may be able to recognize it. Once that is done you can probably (if it is still in print) get a service manual. Be advised parts may not be available.

Good Luck on the hunt.

It's not a transceiver in the modern sense. It's a simple flea-power (old term for QRP) 40 meter CW station.

Receiver is a one-tube regen using a 6SL7 dual triode. Transmitter uses a 6SN7 running 2-3 watts, xtal controlled. Whole thing is built in a small box and could run on batteries or power stolen from a BC set.

At one atmosphere of pressure.

> it can exist as a liquid only under extreme
> pressure..what sort of pressure are you talking here?

The critical point of carbon dioxide is 31.1 C and 73.0 atmospheres. So it must be below 88 F and above 1073 pounds per square inch.

Buy a TCXO on eBay (not necessarily an OCXO, unless you can tolerate
long warmup times and/or can leave it on 24/7), then run it through an
LT1016 or something similar. High-grade crystal oscillators with
square-wave outputs are pretty rare.

There is a certain amount of phase noise, which may or may not be a problem for some applications, but hey, for three bucks! The amount of phase noise seems to be a function of the frequency, which I suppose you would expect.

The other problem is that they aren't actually available on ANY frequency. You can get awfully close, but if you need a pair of oscillators a few hundred hertz apart it could be noticeable. It's not entirely clear to me what their resolution is in programming the rascals, but it seems to be in the neighborhood of 200-300 Hz. If you call DigiKey before about 6 PM their time, they will be able to tell you how close to your frequency they can get.

I've used them quite a bit, and they have their charm, and their limitations.

For a mixer, especially for CW, I think I would stick to one of the little cans if you can get one in an appropriate frequency. They are more expensive, but they are not going to break the bank. DigiKey has them, as well as VCXOs, but only in a limited frequency selection.

Thanks to all the posts on here, I appreciate it. My main desire for this project has been (1) as little parts count as possible and still make a cw qso that is fairly reliable, which to me, a couple hundred milliwatts goes a long ways, which is easy enough to achieve with one trx.(2) stability...a good xtal controlled reciever, also. (3) compact, small enough to put in a little asprin bottle. I realize surface mount cant handle as many mills, but sure would condense things! (4) Above all, different...Ive not seen this in any of the qrp mags! So this would be a little rig that is rock solid, and can have fun with anywhere. Im still working on it! Its just that I cant get it to detect as well as a regenerative rx!I can barely hear loud stations. Ive built lots of things, a g-g 4-1000 amp from the ground up, worked on first try, digital readout receivers, AM transmitters, ya know just having a blast with this hobby. Sure , I could ask myself, why do I bother with such things? I can go out and buy a hot performing radio for a couple thou, right!? And then what? Blab to everyone about how many knobs there are on the front panel? One could also make the point of why even use amateur radio for communication when there is a phone sitting on the operating table that has no trouble with the ionosphere, and you dont have to take turns talking. Its all got to do with what you enjoy! So enjoy it! 73 Doug

2496. my experiment with ultra-sonic transducers as an i-f

Recently took a d-c reciever and put a "transmit" transducer in place of the speaker. Transducer was around 40 kc. Next to this I put the "recieve" transducer. So I had an i.f. of 40 k.c. After this, the signal went into a diode ring mixer, which used audio transformers and 4 1N914 diodes. I injected a signal from a 555 timer(bfo signal) into the mixer and adjusted its frequency until I could hear signals. The results were really impressive, very steep and selective, and even passed one sideband! but images were really close cause of the low i.f.. None of this is really new, cause its the basis of a mechanical filter, but what had me baffled was the fact that with the bfo off, The transducers stripped the carrier off all the signals and am sounded normal!

This info from another post on another thread might be of interest...

The new issue of Worldradio Magazine (Oct '02) page 59 shows a new VFO kit from Datak (<www.philmore-datak.com> click on new products, look for part number 80-1410) that is said to eliminate virtually thousands of crystals. Frequency change is made by changing resistance, using a potentiometer. Suggested price is $15.99.

Adv. Blurb: "This new Basic VFO is intended to be used in place of crystals
in transmitter and receiver circuits.....will provide a low cost precision oscillator that could be used as a switching power supply clock reference, in addition to use as a fixed crystal oscillator replacement.....can be assembled in about 20 minutes and is supplied with parts for using the circuit in the 40 meter band. It will tune from approximately 6.9 to 7.2 MHz as supplied. Instructions are supplied on how to swap out a resistor and capacitor making the circuit usable from 100 kHz to 33Mhz. Also included is a circuit schematic for a 40 meter 5 watt transmitter than can be used with the VFO circuit. It will operate on any DC voltage from six to fourteen volts and draws approximately 140mA.....it employs the new LTC1799 IC."

You can try, but a lot of news servers don't carry binary files in
non-binary groups like this one. Try posting in
alt.binaries.schematics.elctronics instead... or better yet, stick it on
a web page somewhere and post a link.

If anyone is interested in building Jesper's Mini DDS:

http://www.myplace.nu/avr/minidds/

I've designed a PCB for my own version of it:

http://www.geocities.com/leon_heller/minidds.html

and can supply the schematic and PCB artwork (free) if you want to build
your own.

I could put together a kit with all the components, including a PCB, a
pre-programmed AVR microcontroller and detailed instructions for $55
including airmail postage. Unless I'm flooded with orders, the PCB will be
home-made. I won't include sockets. The AVR is user-programmable via the
5-pin Molex connector, BTW, so you can put your own code in it, or modify
Jesper's, if you wish.

Some applications are: precision LF signal generator, reference oscillator
for a very high-res PLL synthesiser and an exciter for an LF transmitter.

73, Leon

SSPAs:
* Original frequency range: 3,475-3,493 MHz, but usable on 3,400 MHz
without modification.
* Gain at 3400 MHz: ~42dB using 4 stages.
* 1 dB compression point: >11 watts @ 9.4v.
* Saturated output: >14 watts (>20 watts may be possible, see below).
* RF connectors: Female SMA.
* DC connector: 15 pin D-type.
* DC supply: +9.4v @ 5-7A (pins 7, 8 & 15), +12v @ 25 mA (pin 12),
-12v @ 75 mA (pin 5) and 0v (pins 2, 6, 13 & 14).
* Control: mute i/p (pin 4), PSU reset o/p (pin 3) temp monitor o/p
(pin 10) and error O/P (pin 11)
* RF O/P power Monitor: upto 10v (pin 1) into hi-z and return (pin 9)
* Size, excluding connectors: 180 x 112 x 26 mm, milled box.
* Weight: 750g.
* Originally the unit was designed for digital modulation, rather than
SSB, a number of people have modified the bias arrangements (not tried at
the radio club) and increased the supply to 10v when it has been suggested
that 18-20 watts is possible. We have increased the supply voltage to 14v
on some units when over 20 watts saturated obtained, but perhaps not
recommended for a long life. The +9.4v supply should not be applied without
the -12v supply on. We also have isolators available, which perform okay at
3400 MHz. It is interesting to note that the unit tested performed better
at 3400 MHz than the intended frequencies.

The club is selling the SSPAs c/w one isolator and DC cable for £50 each
plus UK P&P (@£5)

For photographs of the units go to www.sbrs.org.uk/amps

Hi,

I bought a roll of 0.020 diameter solder at a flea market. This is
Kester Sn63 core 66 flux 282.

Can anyone tell me about the flux? I tried the Kester web page and old
catalogs, but have no idea what kind of flux this is.

Is it suitable for SMT work? Washing?

Thanks for any help.

Google on "kester flux 282" and you'll find out lots.

Any potential is automatically a true negative resistor, since it is a
free harmonic set of bidirectional flows of EM energy (due to its dipolarity
and the broken symmetry of same; it takes the energy right out of the vacuum
via the broken symmetry of the source charge or dipolarity). Hence you can
collect as much energy from it as you wish, from its "flowing rivers of
energy", if you arrange for enough charges (buckets) to collect it (to
collect the water). Nothing says you have to use just one kind of charge
(the electron). You can use -- as Bedini does -- both the ions between the
plates and the electrons in the external circuit. And you can use them
both, and potentialize them both simultaneously with the same potential.
HOW MUCH EXCESS ENERGY YOU CATCH IN BOTH DIRECTIONS DEPENDS SOLELY ON THE
MAGNITUDE OF THE PHI AND THE MAGNITUDE OF THE Q's.

Source record: 41276

Really nice capacitor bank with board and eq resistors already
mounted.
It has the screw type filter capacitors. They are mounted on a
commercial made PC board with eq. resistors. It consist of 15 -
1500mfd @ 450vdc
computer grade capacitors in series. There is room for one more cap,
of
which I have a couple of spares 17 total caps. There are also some
extra resistors mounted on the board you could use to add the last
one.
That would give 93 mf at 7200wvdc. That is nothing to sneeze at! Most
of the HARD work is already done for you.
Great for your next high powered project. It will fit in a standard
19" rackmount chassis it is 6" tall 9 3/4" depth
Figure about 25lbs packed weight shipped from 28681 would like 150.00
+ shipping open to offers I could use 2 oil capacitors around 20mfd @
5000vdc each Ok if cap is higher. ni4l@charter.net

2514. Re: TCXO/OCXO sources

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-23 03:44:43 UTC
From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <ammvnd$ht8$1@slb6.atl.mindspring.net>
Source record: 41282

I think the big question is, how precise of a reference is needed for
this project?

The computer timebase oscillators are usually something like +/-100 PPM
which is a rather large error if you are using it to synthesize a 100 MHz
LO.

Potentually up to 10 KHz error which is pretty poor by todays standards
for a synthesized radio.

==========

OK, so if you are using a DDS which I think I recall from one of the
other posts, a trick I've seen is to measure the actual error and then
program a correction factor into the microprocessor you are using to program
the DDS. You can program in any correction factor required and more or
less hide the off frequency timebase.

Although, this doesn't compensate for how the cheap oscillator is likely
to wander around over temperature.

Hmmm.... Now that I think about it, if you have a temperature sensor and
feed it into the control computer, you could also program in a correction
factor for temperature.

I've seen designs that use a temperature sensor to detect the crystal
temperature and use that to look up a correction factor in a prom which then
controls a DAC to pull the crystal back on frequency.

A homebrew version of this takes a fair amount of time to measure the
correction factors and then program them into a prom lookup table, but it
isn't TOO hard to do and it'd allow you to have a very precise TCXO.

Yeah, I know.... What do you use to verify the frequency while plotting
the correction factors?

Well, the simplest is to zero beat against WWV. Not super accurate,
but with the right setup you ought to be able to do somewhere around 1 PPM.

==========

This would hide a lot of evils in the reference crystal oscillator by
using software.

Although I make no promises for phase noise, that's a function of the
crystal orscillator itself and you can't fix that through software.
Still, for an HF radio, it should be good enough.

==========

However, I think a more accurate, or at the very least settable, oscillator would be a good choice. For a one-off homebrew project you may find a TCXO on ebay. Those are usually pretty good, and they generally have a way to set them precisely on frequency.

Remember to check the synthesizer you intend to use, a lot of the designs allow for setting the synthesizer IC for different reference frequencies by changing the internal reference divider chain. This would allow a larger choice for the frequency of the TCXO you'd look for on ebay.

Seems to me, cellphones are supposed to have pretty good reference oscillators but I have no idea what frequency they usually use.....

Alternatively, you could buy just a crystal and construct your own oscillator circuit. You may have trouble setting it up to allow setting on frequency, but you can get a heck of a lot closer than +/-100 PPM.

I think transverters are used for increasing the working frequency not decreasing it, i.e. passing from HF to VHF. I never saw plans for passing from 10m to 20m or even 80m. The contrary would be easier as 10m is an harmonic of 20m or 80m.

For low to medium power applications you can make a directional
coupler by running the signal through a microstrip transmission line.
On both sides, parallel to the main transmission line two coupler
links are also etched. The parallel section of the link must be well
below 1/4 wavelength (remember the velocity factor in the stripline),
one end of the coupler link is grounded through a 100 ohm termination
resistor, while the other end goes through a diode and low pass filter
capacitor to the meter.

The termination resistor and diode should be good quality surface
mount components. One coupler link will have the terminating resistor
close to the transmitter side connector of the main transmission line,
while the other link has the terminating resistor near the same end as
the antenna connector of the main transmission line. In this way both
the forward and reflected power can be measured simultaneously.

For higher powers, insert the links just under the braid of a section
of coaxial cable and connect the terminating resistor as described
above. For higher power and higher precision make a large 50 ohm
coaxial line of two concentric tubes with proper tapering at both
connectors. Make two slits in the outer tube and insert a coupler
running parallel with the main transmission line in through the slit.

For even higher precision, get a commercial directional coupler, which
usually have N-connectors in the main line and BNC/TNC/SMA connectors
for both ends of the coupling links (4 total). In one BNC plug, insert
a good quality 100 resistor to ground and in the other insert the
diode and the bypass capacitor in the other plug and get the rectified
voltage out. On the other side connect a terminating resistor and the
diode in the opposite ends and this way you will get both the forward
and reflected power.

I guess that you did not find anything if you searched for "SWR", but
try instead searching for "directional coupler" and "reflected power",
since VHF/UHF enthusiasts seldom talk about SWR.

At least in England, there has been kits for allowing 2 m multimodes
(such as FT-290) access to the HF bands using a transverter.

>The contrary would be easier as 10m is an
>harmonic of 20m or 80m.

This is just a situation you try to avoid.

For instance a transmitting converter from 28 Mhz to 144 MHz often
suffers from these harmonics. Assume you want to transmit on 145.100
MHz on a repeater input and you set the HF radio to 29.100 MHz. The
5th harmonic of that is 145.500 Mhz, which falls in the middle of the
FM calling channel :-).

Thus, you have to be very careful to filter out any 5th harmonic from
the HF signal and also take care that the mixer does not generate any
larger amounts of 5th harmonics of the input frequency.

In general you should design the frequencies in such a way that no
harmonics from the low frequency signal or the local oscillator signal
fall close to the desired output frequency band, since it would be
very hard to filter them out, once they have been created.

Toko have these for I.F.'s of 6m or 2m. The difficulty of using 10m
I.F. is that of keeping mixing products out of the TX output. For
Example take IF of 28.000Mhz mixed with 31.5Mhz to give 3.5Mhz
(difference) and 59.5Mhz (sum). The Eighth harmonic of 3.5 is ?? what
?. Now work out other combinations for the n* sum +/- n*diff) etc etc.
And then do the same for all the other HF bands. Not a pretty sight.
The 2m I.F. version would be a lot easier to keep clean.

Completely right. My post was only general.

And I didn't know there was rigs transverting VHF to HF. I thought it was too hard in terms of filtering. Sorry for making confusion.

2520. About AF derived AGC

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-23 12:40:32 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <amn240$71o5b$1@ID-61331.news.dfncis.de>
Source record: 41283

I read a little about AGC and that audio-derived AGC is better than IF-derived in so far as the gain compensation is precisely according to what is actually heard, whereas with IF-derived signals that get through the IF passband but not the audio filtering can cause unwanted gain reduction of the heard signal. The disadvantage with AF-derived AGC being that low frequencies take a relatively long time to reach their peak and during this time the early RF stages of the receiver may already have been overloaded.

My receiver (http://www.hanssummers.com/radio/polyphase/index.htm) is direct conversion using a Tayloe switching detector and polyphase network for opposite sideband suppression. All the selectivity and all the gain are in the AF section, there is no RF amplifier and no IF. Therefore I HAVE to use audio-derived AGC. Since I have no earlier stages for strong signals to overload before the peak is reached, is there going to be a problem?

Alternatively, I had the idea that the post-audio-filter audio could be mixed back up to say a 50KHz "IF", band-pass filtered and rectified to provide the AGC - a simple switching mixer could be used and double-sideband wouldn't matter as all that is needed is the amplitude. 50KHz would be low enough to use ordinary opamps for a simple 50KHz band pass filter and rectifier. Does anyone think this would 1) work and 2) avoid the problems with AF-derived AGC? If there's even going to be a problem with a direct conversion receiver?

Build yourself a 2 meter "J-Pole" from 300 ohm twin lead. Seal it into
a piece of 1/2 pvc pipe and use hose clamps to fasten it to the bike.
Do a search on the web for j-pole and you should come up with many
suitable designs.

Dear Hans,

I also have a home-made Tayloe receiver and it works fine. Now, about the AGC. The other day I found in the Italian magazine "CQ elettronica" for March 2002 an interesting solution which I tried and I am quite satisfied with it. It first amplifies the AF signal with a TL072, then rectifies it with two diodes (voltage doubler) and leads it to an emitter follower with a BC237 (which has an S-meter in the emmiter, and at the same time its feedback positive volatage is routed to the base of another BC237 transistor whose emitter is grounded. The signal shorts the collector-emitter channel when necessary. The collector is connected to the antenna through a 10000 pF capacitor, so in fact the antenna signal is weakened. (When working, the emitter-collector resistance of that transistor changes between 10 kohms and 20 ohms.) It can be added to any receiver without any changes in the receiver.

Unfortunatelly I do not have a scanner to send you the scheme, but if you wish I can send you the article by ordinary post. It has a PCB and a photo. If you are interested, send me an e-mail.

Best wishes, Bozidar, 9A2HL

I have built a polyphase DC RX some years ago which used NE602s in the front end mixers. It had an 8 pole network which gave good SSB suppression out to 8 KHz or so. It used an audio AGC system which seemed to work quite well - in fact Rod VK6KRG still has some boards somewhere. As a bonus the AGC volts gives quite a good approximation to a log detector for an S meter.
Due to the poor performance of the 602's with strong signals this was a problem on HF. I even used the polyphase network at RF to generate the quadrature LO signals - it was quite accuarte to 15 MHz or so but is rather lossy. However you didnt have to have the LO at 4 times the wanted freq.

Hi All,
Just preparing for those long winter nights (!!) and collecting parts for my linear and psu project.
Has any kind soul out there in the UK got a small supply of the PET 200 floating plugs and chassis mount sockets, please - at sensible prices?
Thanks for having a look.
Alternatively, anybody know who sells them as surplus?
Cheers,
Bob

on a VHF newsreflector was also mentioned DF9LN oven-controlled
crystal oscillator. More details found on internet, but I've
forgotten the URL for DF9LN's site

Believe DF9LN's oscillator was only supposed to operate on 10MHz, but
his ideas might be useful for other frequencies like 96MHz

I believe it is exactly the opposite. Strong signals that do not get
through AF filtering and thus do not generate audio-derived AGC
voltage can overload preceeding stages. AGC should be used to
maintain appropriate gain distribution and SNR and not necessarily to
maintain constant audio output.

|The disadvantage with AF-derived AGC being that low
|frequencies take a relatively long time to reach their peak and during this
|time the early RF stages of the receiver may already have been overloaded.

Exactly.

I'm not sure what you are asking. Are you debating between pre-filter
and post-filter AGC? I would think that you would want to feed your
AGC with whatever you are hearing (post-filter) because that's why you
have AGC in the first place. If the previous stages overload, add an
attenuator or use a smaller antenna, don't try to control the gain one
RF cycle at a time. You could also add an FET on the RF input as an
AGC-controlled attenuator, and in combination with the post-audio AGC
should solve the problem before it's a problem.

But the best idea would be to just build it and find out what really
happens -- no point in solving problems that may not exist.

>Alternatively, I had the idea that the post-audio-filter audio could be

>conversion receiver?

It would probably work. I may be missing something here, but it sure
seems like a mighty extensive kludge when you can get the same results
with a much simpler design: If you are trying to prevent RF overload,
add an RF limiter on the front end.

I believe that the AGC voltage you get when you rectify the 50kHz modulated signal will represent the amplitude of the carrier (which is constant) and not that
of the modulation.

In my case all the gain is at audio and I do not think there is much risk of
overloading the mixer etc since it is a FST3253 switch. My main reason for
AGC is just to maintain constant audio output.

I think the Tayloe mixer is great, it doesn't seem to have any strong signal problems. I built my 8-column polyphase network according to design guidelines in a 1995 QEX article. Unlike most networks which either use a constant resistance value or constant capacitance value, in this case both vary in such a way that the network can be made lossless. I measured the loss of the network and it was essentially 0dB within a couple of dB, see my graph at the bottom of http://www.hanssummers.com/radio/polyphase/index.htm. It seems doing this overcomes a common objection to polyphase networks i.e. that they are lossy.

I don't think previous stages are going to cause overload in my case as it
is direct conversion with a switching mixer. What I'm interested in is
keeping the perceived audio more constant, in which case it sounds like I
will be fine with audio derived AGC and a gain-controllable amplifier in the
audio path, I have some CA3086 transconductance opamps for this purpose.

True, true. Just a crazy idea I guess. I will stick to simple AF-derived
AGC and a CA3086 gain-controlled amplifier.

True, though I suppose if one used a balanced mixer the carrier would be mostly suppressed. You could also subtract the constant voltage representing the carrier amplitude. But I think it is all unnecessary complication and I am best off sticking with simple audio AGC.

This is a question frequently encountered on rec.audio.tubes and on www.diyaudio.com In my old Hallicrafters Linear, the mercury vapor rectifiers did the delay for you.

I would suggest the Amperite time delay relays -- these are often found on EBay for various time delays and voltages --

For one of my lab supplies, the manufacturer has placed a 10 ohm resistor in series with the transformer primary. There is a relay across the resistor, and the relay coil is actuated by an RC delay circuit.

If you have been looking for the Ultimate Roller Coaster Inductor,
HERE IT IS !!!

Dimensions:
* Coil element diameter - 3/8"
* Coil winding diameter - 5 11/16" OD.
* Coil frame length -6 13/16"
* Overall length (shaft end to end) - 14 3/4"
* Overall height - 7 1/2".
* Shaft diameter - 3/8"
* Mounting length -13 1/2"
* Mounting width - 7"

37 COILS 103UH
COILS SILVER PLATED
SMOOTH ROLLER ACTION

This is a very well Built Heavy Duty roller inductor.
The name says it all Gates/Harris.
This came from a 10kw transmitter.
It is in excellent shape, no signs of any arcing, coils not pitted or
damaged in any way. Just right for your next project. 225.00

Buyer to pay postage/insurance figure around 17lbs shipped from 28681

Actually, up-conversion has the advantage of fewer potential for birdies
from harmonics of the oscillators. Most of the better transceivers use
an IF higher than the Fo.

I have no experience with the 10m radio you mentioned, but it sounds
like your project has potential. Additional circuitry could be built into a
housing extension, replacing the bottom cover? The down side, It
could cost more than buying a used HF multi-band rig, but that idea
never scared any hot rodders from building. Sounds like a neat
project.

The AGC circuit we used was nothing special.
The gain control element was a T attenuator with a darlington pair to gnd as the control element (ie the vertical part of the T). This was followed by a standard opamp (TL081) for gain in the loop and a transistor/diodes for the DC rectifier at the output of this. It has a control range of better than 60 dB

I understand your situation, however, you are the one that brought up
the comparison between i-f and audio-derived AGC. I was responding to
your comparison, in which I believe that you came to a wrong
conclusion.

In your specific case, audio is the result of downconversion and can
be considered the "i-f." Even here, my comments about appropriate
gain distribution apply. You should have some delay (amplitude, not
time) in the application of gain reduction to allow the SNR to
increase. This means that you cannot maintain a completely flat audio
output. Nor should you want to. Stronger signals should sound
stronger than weak ones.

Depends on your time constant, no? I can picture great fun following the
BBC's six beeps on the hour. Any pause in speech/modulation will let the
smoothing capacitor discharge. Kinda like the breathing in some noise-
reduction hi-fi methods.

No problems with that idea presuming we are not talking extremes of frequency. Solder the box inside and out to make sure that all the copper surfaces are connected. Assuming the sides sit atop the base and support the lid, then you may want to consider connecting the top and bottom faces of these bits together.

If all the faces are connected together then there is no capacitance to worry about. Soldering inside and out assures good short earth paths (the thickness of the board). It's for you to decide if these path lengths are significant at the frequency you're using.

I've used this method many times to create small screened enclosures with no problems.

Good luck

At room temperature, it's a couple of hundred PSI, not extreme at all. You can get liquid CO2 in an ordinary compressed gas bottle (which normally hold gas at around 3000 psi as I recall). It comes with or without a dip tube.

That's an important distinction. My experience is that if you try to control the RF or IF gain with an audio-derived signal, it's just about impossible to get decent operation. If the AF pickoff point is earlier than the audio filter, then the gain can be reduced by signals that are outside the AF filter bandpass. If you pick off after the AF filter, the delay in the filter makes it impossible to get fast AGC operation, and loop stability becomes a problem.

The only good solution I've seen is to design the receiver so that all stages before audio are strong enough to handle whatever signal gets in, and don't try to control the gain of these stages with the AGC. Then use an AGC controlled audio amplifier to maintain the audio output level. I know there are a number of satisfactory circuits around -- probably some in the form of a single IC -- hopefully someone can point you to one.

Message-ID: <3D90D949.2030209@eznec.com>
Source record: 41230

The optimum shape is a circle. The reason is that the loss is least for the shortest conductor length, and the radiation resistance is highest for the largest enclosed area. A circle gives you the most enclosed area for a given conductor length, so that shape gives you the best efficiency.

Agreed. Beginners building from scratch should start with separate
transmitters and receivers.

It is really a project for those of us with the experience and
> patience which takes years to develope.

But even when it's finished, you'll need extraordinary patience to get any
contacts on the thing. Ultra simple transmitters are ultra simple until you
add the telephone needed to pre-arrange contacts! No fun at all!

See http://home.alphalink.com.au/~parkerp/qrpequ.htm

for the definitive words on what's required in a rig that is not only simple
but FUN to use. Unless you want a novely rig to show off to your ham mates
(but not to use) ignore any of the advice given at your peril!

Sure. I don't know enough about AGC which is why I am asking the question
and trying to learn more. Whilst in my case I have to use some form of audio
derived AGC I am still interested in both methods and the comparisons
between them.

I am interested in why you say I shouldn't want to maintain a flat audio
output. If I'm sitting there and there's QSB on the band surely it's nice
for me if the receiver compensates for it as far as possible by keeping the
audio relatively constant?

Hopefully this is the situation I'm in - I think the earler stages in the
receiver are strong enough. The Tayloe detector + polyphase seems a very
clean design.

What you could do is make an AGC circuit with variable attack and
release. Use a faster response for audio, and a slower response (or
switch it out) for CW. This should satisfy all your requirements.
Instead of an AGC circuit, you could probably just plug in a cheap
compressor, like an Alesis or something else along those lines.

One reason to NOT maintain a flat audio output is what happens to general band noise...

If you have massive AGC, then when you are not tuned to a station, the AGC will raise the background noise to the full audio level and you get constant noisy hissing and crackling in the speakers.

If you apply agc slightly to the really weak signals then it won't raise the noise so much when you are not recieving a signal.

Generally, most signals you want to hear will be loud enough to be in AGC range, but really weak ones will be 'fainter' since they may be just barely above the noise and that actually sounds better to the listener since the slight differences in how loud the signal is gives a sense of how powerful the other station is.

GREAT CAESARS GAOST:

Suppose there exists a "group" within the group there exist a
"pac", and the pac is infinte in nature, the group is then undefined.
From a "deck" remove 54 playing cards and cut it in such a way as half
are face up and half are face down. The down cards are now undefined,
and flipping the top card over on the "pac" you are now invisible...
Flip that deck over and begin: is that your card and so on?
Experimental results are often circumstantial!

Hello!

How to make this as short as possible... I have neighbours who insist on playing their stereo at distortion levels. Anyway, I've been told the freq CD players work from is 4.2MHz. Can someone suggest/point me to a circuit for a simple transmitter. Cheap and nasty is fine - just something that say, plays a squeal @ 4.2MHz. Then we can switch it on when they are being unreasonable.

(There's a lot more to this story... Suffice to say the usual methods are of no use - the neighbour has a teenage daughter and both have mental problems - violent types.)

Thank you for reading...

Allan.

I'm sure you have other options other than resorting to intentional
RFI. Try looking up local laws regarding noise pollution and public
nuisances.

I would definately like to post about my first qso but i am still without..
Not for lack of trying or help from others.. THere is a problem with my
rig...I am not hearing anyone sending back to me... Of coarse i've tracked
the problem down to a shorted switch i was using to switch in and out one of
the caps on my crystal.. But soon as i get some time hopefully soon i will
be able to fix that problem...
I'm reqiring all the off board conections and adding a riser for the board
instead of letting it sit at the bottom of my lunch box.. (lunch box is
coated with black elec tape) so i can easily switch the crystals and stop
breaking conection wires..

2581. Noise Figure question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-25 16:15:29 UTC
From: jim.bolinger@lintek.aeroflex.com
Message-ID: <8d5ec8a2.0209250815.393c5e39@posting.google.com>
Source record: 41244

In classic noise figure theory, the noise temperature at the output of a device is given by:

(Ta+Td+Ti)Gd

where Ta is the ambient temperature, Td is the noise temperature contributed by the device, Ti is the input noise temperature, and Gd is the gain of the device (linear units).

If a loss (attenuator) is used as the device, the noise temperature of the attenuator can be determined by:

Td = Ta/Gd-Ta

This allows you to treat an attenuator the same as an amplifier when analyzing a multi stage system for overall noise figure (which I will not go into here).

Plugging this into the first equation results in

(Ta+Ta/Gd-Ta+Ti)Gd = Ta+TiGd

...and the results would be as expected in a multistage system (noise figure degraded by amount of attenuation).

My question, however, is: What happens if one of the stages is an antenna? An attenuator is a 'passive' loss. By that, I mean that its noise is thermal noise, not caused by any active components.

I see nothing in equation 2 above that prevents Gd from being either greater or less than 1.0, so my conjecture is that, yes, an antenna can be treated the same as an attenuator in analyzing a multistage system.

Any thoughts?

Jim

Yep - as I said, there's far more to the story. They're not the full
dollar and if they ever knew I'd called the police - or even (gasp)
TALKED to them and asked them to turn down the music... Let's just
say their friends are the town thieves/drug pushers etc. Really I'd
rather the low power transmitter solution. That way, they simply
think there's something wrong with their stereo - and as long as they
listen to it at a reasonable (not inaudible) level, IT doesn't play
up. No violence, no trouble. Also, we're in an area of Australia
where the "RFI" wouldn't affect anyone else. (A regional area.)

Thanks tho'.

Can anyone help?

Allan.

The method used in early color TV's might be most appropriate (IF you can find the parts!). They used a varistor (negative temperature coefficient thermistor) in series with the primary of the power transformer. On powerup, the varistor limited inrush while it heated up. After a few seconds the varistor heated up, dropped in resistance, and passed nearly full line voltage to the transformer.

|
|I am interested in why you say I shouldn't want to maintain a flat audio
|output. If I'm sitting there and there's QSB on the band surely it's nice
|for me if the receiver compensates for it as far as possible by keeping the
|audio relatively constant?

Well, you're hedging a bit by saying, "relatively constant", where
before you said, "My main reason for AGC is just to maintain constant
audio output.."<g>

There are at least two possibilities.

One, your r-f/i-f subsystem cannot handle the full dynamic range of all possible incoming signal levels so you need some gain control on the front end. This could be in the form of an AGC-controlled PIN diode attenuator, etc.

Two, (your case I believe) the r-f hardware is strong enough to operate at full gain regardless of incoming signal strength. I'm dubious that this is possible but that is just my opinion.

In case one, there should be some threshold, below which no AGC is developed. This maintains the noise figure of the first r-f device, whatever it is. (I realize that at say 160 meters the SNR is set by external noise, but I'm speaking in the general sense.) This is what we mean by "delayed AGC"; the application of control is delayed until the signal level reaches some threshold. Clearly, if this is the case then you cannot maintain a completely constant output without major audio AGC and the resulting problems of loop stability and the effects that I describe next.

In case two, your ACG system becomes nothing more than an audio compressor. If your goal is constant output, then with no signal, you get max noise out. When a signal comes along it just punches a hole in the noise. For a good example of this listen to the guys (Italians leap to mind) that transmit using a lot of compression and set the audio gain wide open and sit across the room. You get to hear the blower on the 10 KW amplifier, the wife in the next room and the dogs barking in the street. When they finally say something the compression kicks in and the noise subsides.

If we use your hedging position, of "relatively constant", then we seem to be in agreement. There can be some area in the dynamic range where the system gain is constant, thus stronger signals sound stronger than weak ones.

Regards,

Wes

I posted what I did because I have already been in a similar
situation. They are going to play whatever they want, whenever they
want, and as loud as they want -- behavior consistant with lawless
attitudes. If you cause RFI (whether they realize it or not) they are
just going to get a new CD player that isn't affected by RFI. If you
manage to jam that one, too, then you can bet they are going to get
suspicious, and you will be risking the violence you claim to be
avoiding.

But hey, if you want to do things the hard way, that's your choice.
Just find yourself a coarse metal or wood file, a screwdriver, and
some jumper cables. Hook the file and screwdriver up to a car battery
with the cables, and draw the screwdriver over the file. Makes a
really nasty hash that can be heard for a couple hundred feet.

More likely to vaporize the screwdriver tip and send fragments of molten
metal into your eye. Bad idea.

He'll have to either call the police, or move.

This story reminds me when I was student. My neighbour was TV addict and this damn' box was playing very loud all the day. So during my examination days, I used to take my heterodyne (and microphone) set up on the IF frequency of the TV. She thought the police was speaking in the TV specially for her, found the sound too loud and that they will destroy the TV with their remote transmitter. So the problem was cured for one week.

bye.

I know this sounds extreme, but I don't think any xtal should be driven this hard. HC25's will be worse than FT243's, but they will both suffer from the large drive current/power. I was unfamiliar with this when I built my first rig, but I learned it later after many years of experience. A simple two tube approach should get you where you want to be. Try Bill Orr's book, "Radio Handbook" or look around for "Electronics Illustrated" or "Popular Electronics".

That MIGHT not be true; I once had a roommate who insisted on turning his stereo up real loud right after I went to bed. But I found that I could "play" with the switch on my electric blanket, thereby creating "static" on his stereo, and he soon turned it off. To my knowledge, he never connected that "static" to my going to bed!

For a relativley high current homebrew 12v PSU (150A) using a
toroidal transformer. I took a second ,small, 12v Transformer to
switch a control relay through an RC network. the R was sized to give
a 5 second delay before the relay switched a ballast out of the
primary of the power transformer. for ballast I used a, IIRC, a 100w
tungsten filament lamp in series with the primary of the power
transformer.
I'll refer to my notes for specifics if requested.

Hello Mike,

Study completed some time back and put into the form of a small program.

Download program MAGLOOP4 from website below in a few seconds. Not zipped up. Run immediately. User friendly. A 2-week user training course is not needed.

In a list of other interesting characteristics, for given loop circumference and conductor diameter, this excellent program calculates efficiency of regular shaped loops: triangle, square, hexagon, octagon, circle.

As a little extra, for rough guidance on what might be expected under ordinary ionospheric conditions, for given transmitter power the receiver S-meter meter reading on 1-hop daylight and 3-hop darkness radio paths are estimated.

A complete magloop design program (except mechanical) - FREE to UK nationals. Recommend it to your friends.

For MAGLOOP4 click now on following website.

>
Td is the device's effective noise temperature (referred to the input),
and Ti is the effective noise temperature of the termination at the
input port. Both of these are added.

Multiplying the sum by Gd moves the effective noise temperature to the
output. The output noise temperature To then becomes the Ti figure for
the next stage.

Therefore: To = (Ti + Td)*Gd (eq 1)

Ta doesn't enter directly into the basic equation at all. Td usually
depends indirectly on the Ta that the device is in, but that's a
different thing.

If the input is a resistive load, then its noise temperature is equal to
Ta... but that's another different thing. You still don't get Ti and Ta
together in the same equation.

>If a loss (attenuator) is used as the device, the noise temperature of
>the attenuator can be determined by:
>
> Td = Ta/Gd-Ta
>
You're confusing gain and loss. In these equations, Gd is >1 for gain
and <1 for loss, but the equation doesn't change.

The effective noise temperature of a purely resistive attenuator is its
physical temperature, so Ta *does* appear here.

The same equation 1 then applies:

To = (Ti + Td)*Gd

which in this particular case translates to:

To = (Ti + Ta)*Gd where Gd<1 because it's an attenuator.

>My question, however, is: What happens if one of the stages is an
>antenna?

An antenna is not a "stage" - it can only be the input to the system, so the antenna's noise temperature is your Ti for the first stage. This is usually written as:

Tsystem = Tant + Trx

The antenna is sort of a noise generator. It has a noise temperature of about the object it is pointed at provided the beam width is small enough. If it is pointed at or near the ground then the noise is about the temp of the ground somewhere around 270 deg K if I remember correctly for a normal room (outside ?) temp. If it is pointed at a clear sky (no stars or radio sources) then it can be very low like maybe 20 or 30 deg K.

Mostly...
Antenna noise temperature is the equivalent temperature of all the noise it sees...still kTB.
For example, NBS (back when it was still called that) and the ITU both have published radio noise curves for HF, for example, that are stated in terms of antenna noise factor fa (which is just Tant/To+1, by definition). fa is so large at lower HF frequencies that HF systems are generally "externally noise limited", and low-noise preamplification makes no improvement.
Getting into VHF, atmospheric noise gets smaller but galactic noise gets larger. Galactic noise at 2m is still in excess of 1,000K if I recall correctly. But it gets small enough that with typical receivers and transmission line losses, preamplification makes a positive difference.
Note that antenna beamwidth only makes a difference if the noise source is much larger in angular extent than the beamwidth...generally only really happens with large radioastronomical antennas pointed at the sun or moon.
As you get over 1GHz, the situation Ralph describes below is pretty accurate.
Since antennas have thermal losses of their own, however, actually the antenna noise factor has to get broken up into two terms:
Tant(efficiency)+To(1-efficiency)
So at microwave frequencies, an antenna pointed at a 20K sky needs to be very efficient to keep the actual antenna noise factor low.

>possible... I have neighbours who insist
>on playing their stereo at distortion levels. Anyway, I've been told
>the freq CD players work from is 4.2MHz. Can someone suggest/point me

Allen, I am not familiar with any 4.2 mhz signal used in CD player..Most likely a transmitter that would interfere with their CD player would probably be illlegal ,and could get you sent to "radio jail"..if the noise or sound level is so high as to be a neusinance to you, you may have a civil case that you could persue.. don`t believe I would get into the interference business, could bother other neighbors, air lines,law enforcement, military ,who knows..good luck HS in Fla.

There's a little web ap here that will calculate the vapor pressure for you at any given temperature (over a limited range): http://www.eatel.net/~amptech/elecdisc/rifledemos.htm This says at 68F = 20C, it's some 833psi. Is that extreme? Perhaps not, but it's enough you should have a proper container for it!

You can find a phase diagram for CO2 here: http://www.chem.uncc.edu/faculty/murphy/1252/Chapter11B/sld004.htm That should give you a bit more insight. Below -56.4C, you won't have liquid, and above 31.1C, the difference between liquid and gas is blurred. And you don't have liquid at pressures less than 5.11 atmospheres.

In fact, I was a teaching assistant in a chem lab long ago, and we had some dry ice in for some reason. One of the students put some in a glass sample vial, and I happened by about the time it warmed enough to become a liquid. It was one of the few times I felt really good, especially after the fact, about having a little forethought about what might happen...I told him to wrap it in a towel _immediately_ and lock it in his storage locker. A few minutes later, we were treated to a fairly loud BANG! from the locker, and he took out the towel and glass shards. So...please do NOT try this at home!

Cheers,
Tom

I dont have any fancy test equipment, but I did try a selectivity
test with my frequency counter, looks like it has selectivity of about
3.5 khz...not great, but then the further away I place the
transducers, the better. 73 Doug

Terrible images, yes indeed! But this idea came upon me as I was trying to come up with different ways to filter the signal. Of course xtal filters are cheap and easy to make, but this was cool to actually use. 73 Doug p.s., dont know how to put the block diagram on here.

This would mean that you could turn the AGC off, run the RF gain at full tilt, use a good antenna, tune across 75 meters on a contest weekend and not have any distortion on the strongest signals on the band.

to
> deliver the required current?

Because as the battery voltage climbs during charging, the current
drops. A current regulator will maintain a constant current regardless
of battery voltage so it gets charged faster.

Or switch in an attenuator, and switch it back out on Monday morning.

Yes, but that represents a form of manual gain control. The
electronics is not capable of handling the full range of possible
signals. My point is that I have not experienced a receiver that can
handle the full potential range of signals without some type of gain
control, be it manual RF gain, an attenuator, or AGC.

Why not visit a local retailer -- should be several in Canada -- and
purchase a Ray-O-Vac NiMH charger? For under US$20.00 you get a charger
that will charge AA, AAA, and 9-volt cells; adjusts the charge rate to fit
the condition of the battery; and has indicator lamps to tell you when it's
finished. Probably less than the cost to build one.

Jan,

Not sure what the ferrite was used for. You describe the basic makings of a crystal set, and for more information on various types try www.midnightscience.com

There is also a book called "The Voice of the Crystal" which shows how to make crystal sets from household materials, no special parts required.

A basic crystal set has some kind of tuner, which is a coil/capacitor combination with either the coil or the capacitor variable, a detector, a set of headphones and an antenna and ground. Sometimes a fixed capacitor or a resistor is added across the headphones depending on the type. Many materials have been used for detectors, but the common device is a 1N34 germanium diode. Headphones need to be high impedance, 2000 ohms or greater. Crystal headphones need some kind of resistor across them as a load for the detector. (Usually about 47000 ohms.) More information on the Crystal Set Society web page mentioned above.

Have fun!

Doug Moore

Nice, it reminds me my first radio.

In this time I used a coil of about 100 turns in parallel with a variable capacitor (500 pF). It was OK for AM. Ferrite may increase sensitivity and selectivity. It's wise not to connect the antenna at the top but at about 1/3 of the coil. The rest is classic: germanium diode for detection (not silicon because of cutoff), 2000 ohms headphones, a small grounding cap (1000 pF) across the headphones. The ground connection (conterpoise) is mandatory because this radio is not that sensitive. You can always get close and not so close AM stations with this and plenty of fun for the kids.

Sort of...
There is also "man-made noise" which can be impulsive at HF frquencies and at VHF takes on a Gaussian distribution and can be summed power-wise with galactic and system (receiver, kToBF) noise. At 144MHz in the suburbs it has an equivalent level above kToB of 20dB, dropping to 0dB at 1GHz; at rural locations it is about 20dB lower. Note, you still have to add galactic noise above about 120MHz where galactic equals rural man made noise. This is from a 1963 CCIR report which is used to predict system performance. It is published in the ITT Handbook (Howard Sams & Co).

The interesting conclusion is that there is no reason to increase your receiver antenna gain if all it is doing is giving you MORE NOISE! In fact, for terrestrial communications below ~200MHz, a receiving antenna gain of more than 0dBi is wasted if you have a moderately low noise receiver (NF<2dB). (Transmitter EIRP is of course a different story.)

So how come people buy all these beams?

If the noise distribution is uniform in all directions, the increased noise power density received by a beam in the forward direction is exactly compensated by the reduced power density received from other directions. Therefore the noise power received by the beam antenna is the same as that received by an isotropic source, which is another way of saying that the antenna noise temperature remains the same.

But the incoming power from the wanted signal is multiplied by the forward gain, because the beam collects more power from a wavefront arriving from that direction.

>(Transmitter EIRP is of course a different story.)
>
Transmitter EIRP is almost the *same* story, only it's rather easier to visualize.

The beam concentrates more of the radiated power in the forward direction, giving gain over an isotropic source. But the total radiated power doesn't change, so in the unwanted directions a beam must have *loss* relative to an isotropic source.

If you want to get creative, how about using one of those fiberglass
bicycle flag poles and setting up a vertical inside it?

Or you could try something from an old CB fiberglass antenna.

Try some of the cb mod pages. The best one to modify, is one that has
either an 01 or an 858 pll chip. I have a trc458 radio shack rig with 3
thumbwheels in place of the original channel selector switch. This gives
me almost all of the 10 meter band and I have worked the planet with 12
watts in ssb and psk31.

Best of luck and 73 for now.

Mike Marcus, N3JMM, has an interesting article on LINUX and "software radio" In the October 2002 QST.

Mark discusses the ideas (from 1959) of John Costas. "John feared that the widespread use of SSB would lead to a rapid decline in HF equipment building by hams and a consequential adverse impact on the ARS...Costas was trying to advocate suppressed-carrier double sideband because it was simpler to build and had overall throughput comparable to SSB according to his analysis."

Having recently built two DSB transcievers and one SSB transmitter, I thought this was a very interesting comment. The DSB rigs are far easier to get going.

What do you guys think -- could simple DSB rigs have saved more hams from appliance addiction?

All history I'm afraid, leading to today where here in the UK Home Brew is almost extinct even simple mods to PMR equipment is seen as being for the very few that have the time knowledge and test equipment, you only have to look at the help files to realise many componants suitable for Home Brew are no longer made,
Of course there will always be a few diehards usually grey heads that will carry on but amateur radio in the home brew sense will for all intents and purposes be gone by the end of this decade, with the advent of broadband internet and all that will come with it communication in the amateur sense will be over, as the younger generation will see no magic in it, similar to us when we turn a light switch on and get light, we are at this moment experiancing the end of an era, like steam trains.......

Let me tie this together with the article in QEX regarding receivers and adjacent channel interference. I think that the article in QEX will cause a lot of people to rething using their transceivers for DX. When a modified Drake R4C comes out on top (because of its very quiet PTO) , you know that 20 years of up-converting is not the way to go.

A lot of "homebrewing" fans have gone into robotics, microcontrollers, audio and "over-clocking" their PC's. I couldn't get my 3 sons into ham radio, but they are all gadgeteers. Just look at the direction of magazines -- Nuts N Volts, Circuit Cellar, AudioXpress etc., etc.

2638. Homebrew in QST--Chicken or Egg?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-27 15:32:40 UTC
From: Roger Leone <arleoneNoSpam@inreach.com>
Message-ID: <9S_k9.1537$hv5.456934431@news.inreach.com>
Source record: 41102

QST ceased being a technical publication several decades ago. If you pick up some issues from the 1950's and 1960's you will be amazed at the construction articles that gave homebrewers many good designs to follow. Yes, QEX is a separate publication for the technically inclined, but it just segregates homebrewers from the mainstream ham population. The Radio Amateur's Handbook also has greatly reduced content aimed at homebrewers.

SSB transmitters and receivers are a little harder to build than those old AM rigs, but better components are available today that simplify the process (DBM's, filters, etc). But you don't go directly to building a SSB transceiver without some easier projects to learn from and whet your appetite. Homebrewers can build power supplies, antenna tuners and other parts of their stations, even if they don't try to build an all band, all mode transceiver.

My question is this: Does QST's lack of technical content merely reflect the preference of its readers, or does QST's lack of technical content the contribute to the lack of interest in its readers? (Cause or effect, chicken or egg?)

I am guessing that it is a little bit of both.

73,

Roger K6XQ (ARRL member and QEX subscriber)

Source record: 41103

: i have acquired some old motorola pageboy pagers that operate on 153.110. i
: would like to use them as a weather alert reciever or as a 2M repeater
: monitor.

Not practical... they are not designed for audio and mod'ing them is a pain. Not to mention the large change in frequency. You can buy a weather alert receiver from Radio Shaft cheap, it's more practical to use it for repeater rx operation adding a squelch circuit. With the cost of scanners near an all time low... you should be looking in that direction.

: the second question i have is on a motorola radio that radioshack used to
: make. catalog 19-1216 uhf business band radio. is it possible to change it
: to a 70cm repeater or simplex freq. i checked batlabs.com and couldnt find
: anything

Yes, don't have a picture of it, but it's probably something like a Motorola Spirit or similar series of radio. Find a motorola person and they should be able to provide you with the equivalent Motorola radio type. Radio Shack should also be able to sell you a service manual for it, they've been really go to me in that regards.

It probably wouldn't be practical to move the radio into the ham bands. Many of them are crystal controlled and require retuning plus. As cheap as ham radios are getting these days, don't waste your time ordering crystals for a conversion.

: any help would be appreciated
: steve

I am a longtime ARRL member (you're supposed to say this instead of
"QST subscriber") and on again-off again QEX subscriber. I also buy a
new Handbook and Antenna Book once in a while and I have all of the
Antenna Compendiums, (and was published in the last one).

In my opinion, the ARRL has turned into a publishing house. The
objective is to sell as many publications as possible. If that means
divvying up the available material into a number of separate
"specialty" publications then that's what they do. Is it in the best
interest of ham radio to do so? I don't think so.

On a personal note, I would have much rather my paper was published in
QST where it would have done more good than have it published in the
Compendium, where the readership is much smaller.

Just examine the advertiser's index in the latest issue for example.
Not counting the covers, there are 160 pages in this "Official Journal
of the ARRL." Seventeen of them have advertisements for---you guessed
it, the ARRL.

To be fair, many of these are nothing more that fillers; however, four
are full-page ads. Take out all of this shilling for the house and
there would have been room for a technical article or two.

As for QEX, as I said earlier, I have subscribed a few times (not currently) but it's too expensive. If there are four good pieces in it but I'm not interested in two of them, then 50% of the content is wasted on me. If these same pieces were in QST, then the two I'm not interested in would be a small percentage of the total. Clearly, the "Official Journal of the ARRL" should be including the work of all of its members and not relegating it to a splinter publication.

I have the first issue of QEX, which offered subscriptions of 12 issues for $6.00. The last issue I have at hand, July/August 2001, offers subscriptions of six issues for $24. Sure the new variant is slick, colorful and has more pages. (Three of those pages, including the back cover contain the inevitable full-page ads for ARRL.)

I saw my first QST in the high school library in the 1950's and was fascinated. I didn't understand much of it but it challenged and motivated me to learn to understand it. Ultimately, my hobby led to my life's work in engineering

Would a young person today be similarly challenged by "The Doctor is IN", which in the current issue says to avoid experimenting with an inexpensive microphone and go buy an overpriced Heil microphone instead?

I doubt it. But I'm sure that the ARRL's market research guys have fine-tuned their offerings to exactly what the majority of the public desires.

I agree with you somewhat Skipp, but the old pageboy can and was used for
monitoring repeaters. Nowadays this is probably something that you
wouldn't want to do as it is one royal pain unless you can get the xtals
and a Pageboy I which had a nice size speaker. All should be advised that
it only works on a single freq and needs modifications up the wazoo for
carrier squelch and voice. Skipp's advise on the weather monitor makes
more sense.

Well said, Wes.

The other issue with respect to QEX is: should its content really be printed and distributed on paper in the first place? I can put technical articles on the Web and reach anyone, anywhere, anytime (or at least as long as qsl.net stays in business), for free. QEX reaches a very limited audience by comparison.... but obviously they contribute editorial value that isn't available on the Web.

What are peoples' thoughts on the value of placing technical content in specialized, non-peer-reviewed magazines like QEX, versus less-disciplined venues like WWW sites? If you were in high school now, you wouldn't be digging through musty stacks of QSTs and QEXes in your library looking for something interesting to read -- you'd be surfing the net instead.

with that much driving power availible, just drive it untuned.
i am doing so right now. i have a balun that is center tapped.
low side to ground, center tap to rig, and high side to grid.
i have 4 resistors in series/parallel set up to provide 200 ohms
from the grid to ground as a load for the rig. full output
equal about 10 watts input

I am guessing from your name that you live somwhere in Norway, and the crystal detector won't work very well, at least not during daytime, unless you live within a few 100 km from some of the medium/long wave broadcasting stations. In Norway they are all along the West Coast and in the North (Stavanger, Kristiansund, ...).

> from appliance addiction?

I don't think DSB would have made much difference, Bill. Here's why:

One of the big attractions of SSB (or SSSC, as it was originally known) over AM was spectrum conservation. Switching to SSB virtually doubled the effective width of the 'phone parts of the HF ham bands. (The US HF 'phone bands were fewer and narrower back then). DSB offered no spectrum savings over conventional AM, just the elimination of carrier heterodynes and big-iron modulators. And the Ancient Ones who pioneered SSB produced many examples of simple SSB rigs, like the W1JEO exciter, "Cheap And Easy SSB", and the IMP 3 tube exciter.

One of the main reasons many hams homebrewed in the post-WW2 era was economics. Prices of manufactured equipment were much higher than today, when you consider inflation. The savings of homebrew/surplus/kit rigs could make a big difference. Manufactured gear of that time was expensive in large part because of the manual labor needed to assemble and align it. New parts were relatively expensive for the same reasons. Homebrewing eliminated the labor cost, and the use of recycled and surplus parts allowed the homebrewing ham to save significant money. A set of simple hand tools and a few pieces of test gear were adequate for most ham projects.

The techology used by most hams in those days tended towards the "lots of boxes" shack: receiver, converter, exciter, VFO, final, speech amplifier, antenna tuning unit, control unit, several power supplies,

etc. Homebrew stations usually consisted of an evolution of small projects, built as time, skills and finances permitted. Often old gear was torn down and the parts reused, or existing gear modified and added onto until it bore little resemblance to its original form.

The end result of all this was that being a ham in those days required a certain amount of technical know-how and mechanical skill unless you were one of the few who were well-heeled enough to buy everything. And even those with lots of dough had to integrate their store-bought boxes into a working station. The prices of those days look cheap today, until you remember how low wages were back then for most people. Back when $5000/yr was considered a really good middle-class income, spending $500 on a ham station was BIG money.

The trend away from homebrewing was apparent even before WW2, and postwar surplus furthered that trend even before SSB became popular with hams.

As electronic manufacturing methods advanced, costs declined. Hand wiring gave way to PC boards. Miniaturization meant greater precision and planning were required. Quantity discounts on new parts and the static nature of surplus
meant that the homebrewers' cost advantages dwindled. This was first seen in the kit market - Heath could sell rigs like the DX-20/40/100 series for less than the parts would cost if bought new in small quantities. (btw, early Heath
stuff is full of surplus components).

On top of this was the move from separate, uncoordinated transmitter/receiver setups to the true heterodyne transceiver and the matched-pair transmitter-receiver lines. Multiband HF SSB ham transceivers were much less expensive than
comparable AM gear. Transceivers were also smaller and lighter, bringing the hamshack out of the basement or attic. But a typical ham transceiver was too complex for home construction with simple tools unless the builder was very
skilled and very patient, and willing to risk lots of time and money on a single big project, rather than lots of little ones. Again, the kit rigs offered a lowcost solution - when Heath offered the HW-100 at $250, it was a rare ham who could homebrew an equivalent for less money.

Where homebrewing flourishes is in the areas where the mainstream manufacturers don't go very much, like QRP, AM (!), vacuum tubes, new modes and methods, truly high performance, etc.

But homebrewing is NOT dead, despite pronouncements otherwise. It's simply become a niche market, rather than something almost all hams did, out of necessity. See Electric Radio for July, 1995.;-)

Hi Ron..

Are you related to Victor Meldrew??

Don't be so pessimistic!

Homebrew is alive and well... viz. UK QRP club, UK microwavers, etc ..
though not to the extent it was when I first got my callsign.

It's up to us "veterans" to inject some magic into the hobby for
youngsters. Communication is only part of amateur radio. There's a
great deal of satisfaction to be gained from making gear for its own
sake.

"Non-peer-reviewed"? QEX does have a review panel, but it's also presently edited by someone who knows his stuff in his own right. That makes you think about what you write. As both an author and an editor, I greatly value someone else's editorial input, and technical article are almost always the better for it.

You don't get that feedback on the web... and web content is generally the poorer without it.

Hello all,

I don't know if I'm in the right place or not, but this is what I'm lookin for. I need to know how to make a transmitter that transmits up to about a 1/4 mile(maybe a little further) and how to build a reciever to go with it. I have NO idea of how to go about this. I just have this "idea" and I need to build a transmitter and reciever to get started. Could anyone point me in the right direction? Websites, books and such? Would greatly appreciate it......Thanks.

Would this be for communications purposes or just a link of some sort?
My first instinct says get a pair of FRS walkie talkies and you could
easily rig up something at very little cost.

Yes indeed. But there is peer review and then there is PEER REVIEW.

My former employer paid a stipend for published papers, although only
those published in peer-reviewed journals (think IEEE). They also
required the author to get company approval before submitting
something for publication.

I once asked whether they would pay for something I was submitting to
a ham publication and they about laughed. I got it published
anyway---without their permission. They wouldn't pay; I wouldn't
play.

|That

Not necessarily. Your web site is a shining example of an argument
against your position <g>. Others include, but are not limited to:
W4RNL, W7EL, W9CF...

These folks publish great stuff and I wouldn't be surprised if they
ran it by their peers before putting it up.

And I believe forums such as this wind up being a form of peer review.

The conventional meaning of peer review implies that articles are vetted
by independent reviewers before they ever see the light of day. That's
a little different from what a magazine's on-staff editorial board does
(for better or worse).

> You don't get that feedback on the web...

Actually, I haven't found that to be true at all. I get a LOT of
feedback, much of it actually useful.

> and web content is generally

I just had a burst of nostagia! I did one of those that exact way shortly
after I got my ham ticket. A friend raved over it so much that I gave it to
him, and he later gave it to another friend who gave it to someone else and
so on. I lost track of it after that, but it sure gave a string of new hams
a lot of fun!

The conversion was basically straightforward. The PLL chip takes as input
4-bit BCD numbers, one for each digit of the frequency. I tore out the the
channel assembly that was designed to present only the correct 40 BCD
patterns for the 40 CB channels. I replaced this with BCD thumbwheel
switches, one for each digit. Then I changed the reference crystal to move
the covered band up 1 Mhz from the 27 Mhz range to 28 Mhz. Then it was a
simple matter of tweaking the thing up to perform well a Mhz higher than
originally intended. I got a mod for tying the "clarifier" to the
transmitter as well as the receiver out of a CB mods book. The end result
was a radio with full coverage from about 28Mhz to about 29Mhz.

$10 for the radio at a yard sale, thumbwheels and a crystal from the junk box, produced a very usable QRP radio for 10 meters.

Ralph:

ARRL Amateur Radio Handbook (various years but not in the past 5 or so) -and- (if my mind isn't playing tricks on me) one of their VHF books - contained an article on VHF/UHF High Power Dummy Load construction. It used two one-gallon paint cans (stacked) and 50 ohm Ohmite Power Resistor (think 225w rated) and some fairly easy-to-make sheet metal cones... I built two of them years ago and they worked very well consiering their "cheap" price... They were good (I think for a Kilowatt out to maybe 450 Mhz... (I used
mine for 144 and 220 Mhz)...

Hope this helps...

There were quite a few modification articles in 73 magazine from the early 70s, I believe QST had one article written by Bob Heil. The easiest coversion is a CB rig with the 02A PLL chip and three crystals. To get it on 10 meters, you change one crystal, realign it, and you're on the air.

Sorry Peter but you are wrong, have you no eyes to see? I have
been going to Amateur Rallies for years and they are declining
fast, and even these rallies are 75% computer, and we call them
grey head rallies, just look around next time you go to one and see
for yourself, componants are getting hard to find, magazines like
HRT have gone, most clubs have a declining membership, I've
seen it all happen, when I started in comms 30 years ago it was
all repairs with a soldering iron, when I retired I was just a mobile
terminal, all I had was a laptop pooter!
End of the decade as I said, you wait and see......

And Wes said:
>there's peer review and PEER REVIEW.

In academic publishing, industrial-strength PEER REVIEW is the rule, but it can be very much a "for better or worse" process. At its best, it provides useful feedback. Anonymity provides protection to the reviewer, in an often small community where people have extensive power over one another's appointments and research grants. All well and good... but at its worst, it provides a free-fire zone for vicious academic conflicts, and anonymity is a sham.

Academic editors grieve over this, but there's nothing they can do to change it.

Unfortunately there are numerous examples where peer reviewing in amateur radio publications has fallen far short of the ideal... which, after all, is to get the best possible article out there and published for the benefit of everyone. In particular, anonymity creates a huge risk of misunderstandings between authors and reviewers, and most editors are in a poor position to mediate in matters of high-technology nitpicking.

All too often the result is that the article never gets published at all. Radio amateurs don't have to publish to survive, like academics do, and I've seen many would-be authors permanently turned off by insensitive and incompetent reviewing processes. Everybody loses.

I haven't been bitten myself by this process, but have witnessed enough fiascos to mistrust it deeply. I won't take part in any amateur radio reviewing process that explicitly forbids me to discuss questions directly with the author.

For my own articles, my policy is now to take charge of the reviewing process myself, so that I can finally go to an editor and say "This article has already been reviewed by <insert list of well-known names>. Any points of disagreement have either been resolved or are discussed in the article." This is another of those things that e-mail makes very easy, and editors are very appreciative.

>> You don't get that feedback on the web...
>
>Actually, I haven't found that to be true at all. I get a LOT of

Roger, you make a very good point. The ARRL has become like AAA and AARP -- organizations which exist to keep the organization intact, with considerable lobbying impact.

>sake.

Peter,

And that is the crux of the matter. Yes, back in the 50's it made economic sense to roll your own, especially if you didn't have any money to begin with. But, though that may have been the reason you started homebrewing, you quickly realized there was real satisfaction in the creation and operation of your own gear. My 50's stations were all homebrew except for the receivers.

Today, there's a lot of competition for peoples time and interest. Basic survival takes a lot more effort than it did in the 50's. I enjoy restoring and operating old vacuum tube gear because it takes me back to a time when things were simpler, and I could see all the parts without a magnifying glass. But, I doubt I'll finish all the projects I have pending before I expire.

Homebrew isn't dead, but it is a shadow of what it once was. As for the magazines, they seem to concentrate on what brings the most revenue, a trend that permeates today's society.

This was known way back in 1957 (see "What's Wrong With Our Present Receivers?" QST, January 1957).

For many years the ham rig designers have traded true "radio performance" for features such as general coverage and memories. Do you really NEED to know your QRG down to the Hertz? Yaecomwood thinks so. But don't try to turn the AGC off.

The R4-C's 30+ year old design is not electropolitically correct today. No digital stuff in it. And it uses vacuum tubes.

Try the Rec.Antiques.Phono&Radio forum. Why tubes does it use?
It probably needs around 22.5 volts on the detector, and I'd guess
45 volts on the first audio, and the second audio plate voltage would
be around 100 volts max, depending on the tube type and whether
a C bias battery is used.

The first and second jacks can be used for either 2K headphones,
or vintage horn or cathedral type speaker--these are also high impedance.
To save batteries, you'd use the jack that delivered usable audio for
the station you were listening to.

Message-ID: <Xns9297607187CF9heyyouclanhobbsorg@130.133.1.4>
Source record: 41136

I'm testing the waters of building from scratch by putting together a Neophyte Receiver (QST, 2/98 reprinted in _QRP Classics_, also available online at http://www.arrl.org/tis/info/pdf/28814.pdf). Figure this is a good way to motivate me to upgrade my ticket, if I can build my own gear.

I've tracked down sources for all of the components except one, which the article describes as follows:

Two-section, polyethylene-dielectric variable; sections 59.2 and 141.6 pF (Mouser 24TR222 or equivalent).

Mouser no longer carries this part number, and I was unable to locate anything similar in their catalog. I did however find the following, and wonder if someone more experienced than I could tell me if it's "equivalent": http://www.elexp.com/cmp_280p.htm

Thanks a bunch for any help!

Air variable capacitors are getting more expensive.

Look at the available parts at Dan's Small Parts

http://www.fix.net/~jparker/dans.html

Th second one of these (that is listed) may be a good substitute. E-mail
your situation - he may have a few single items of the exact part.

w9gb

Hammarlund Dual 6PF - 150PF per section with a 1/4" shaft,
Part number on this capacitor 9411-73-60079, size is 3 1/2" long
x 1" wide (this does not include shaft length), Shaft length 1 1/2"
long. Has Ceramic base, tabbed holes for mounting. These are
new old stock, no longer manufactured. Price $20.00EA.

Small Dual Section Air Variable Capacitor.
Double bearing type has a 1/4" shaft that extends 1/2"
from the front of the air variable. Can be panel mounted
or has tapped holes in the base for mounting that way.
Front section is 8-125PF and rear section is 8-90PF.
Size is 1 5/16" Wide at the front and 7/8" Deep.
A very nice small air variable.
Dan's price $12.50ea.

Jim: Agreed. A simple SSB rig is not that much more difficult. I
liked the IMP. And the transistorized IMP. I recently came across a
great series of QST articles by Doug DeMaw on building simple SSB
transmitters. Circa 1985. Great stuff.

Viva HB! I'm amused by the forecasts of the end of homebrewing.
Unless they kick down the doors and pry the soldering irons from our
hands, there will be at least a few of us still at it.

I think the "parts shortage" is exaggerated. As for the oft cited
time crunch of modern life, I think this is sometimes used as an
excuse by guys who for some reason feel uncomfortable about all the
appliances in theirs shack. (One ham I know ALWAYS says "I wish I had
the time," when homebrewing comes up. He's an avid golfer.) I'm sure
this IS a problem for many people, but there seems to be plenty of

time for CONTESTS! And aren't we always being reminded of the high percentage of retirees in our ranks. Parts shortage? Time crunch? Lets face it, most hams just don't like to homebrew. To each his own. More parts for us!

It's NOT for communications puposes. I just need something that works basically like a garage door opener, and that will work at about a 1/4 mile range. The idea I have is something I want to try to get patented. I need something that when a switch or button is tripped will send out a signal to a reciever that will more or less turn on a light.......The frs walkie talkies might work I guess. I also understand that transmitting without a license is illegal?? (someone emailed me that info) I don't actually have to transmit. I just need to make a working model so I can get everything down on paper for the patent.

Thanks for the info....

2680. Local Oscillator Waveforms

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-28 23:17:14 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <3D96396A.20055B0F@alma.demon.co.uk>
Source record: 41143

I am re-visiting a superhet radio which I built over 25 years ago as a kid! Now that I have a reasonable selection of test equipment, I thought that it was time to dust it off and get it working properly.

The local oscillator uses a single NPN transistor in the configuration where the coil has 3 windings, with the smaller windings in the emitter and collector circuits. I looked at the waveform on my scope and was pretty appalled.

I built on the bench (using a plug in board) another oscillator from the same Babani Press book (BP226 - How to Build Advanced Short Wave Receivers) based on a 2N3819 JFET. The waveforms were also pretty bad, with plenty of harmonics and not a very nice sinewave. As expected the signal amplitude varied with frequency (as did the attrociousness of the waveform!).

I then build a 3rd variation (from a magazine) again FET based, but again the waveform was very poor.

I am aware that a edsktop lash up using plug in boards isn't the best way to try out HF oscillators, but can anybody recommend a reasonably simple circuit that can be used as the LO for a superhet?

I have a suspicion that same kind of feedback based on the signal level might be a good way to improve the waveform, kind of like a Wien bridge oscillator which uses a lamp (in some cases).

Just got back home from Santa Barbara. I visited Marvac Electronics
(http://www.marvac.com) and was quite impressed. These kinds of
electronic 'boutiques' just don't exist much anymore.
They've got a Good Selection of components, tools, cables, connectors,
hardware, project boxes, etc., usw.
I bought a Unitbit (to replace a broken one), 2 cans of freeze spray,
and some new tips for my Weller gun. I wish I had a place like
this within 75 miles of _my_ QTH!
Patronize it, folks. It's be a shame to see it dry up and blow away...

It can be quite tricky to get a decent sine wave sometimes. Colpitts
oscillators tend to be better than Hartleys, but you can get a Hartley
oscillator to behave. You are probably using Hartley configurations. Try a
diode (cathode to ground) on the gate, to limit the signal (not the ideal
solution, but it works). Also, a bypassed source resistor will help. It is
possible to rectify the output, amplify it and use it as feedback to
stabilise the oscillator amplitude. Marconi signal generators used this
approach. Also, you should buffer the oscillator output.

There were even designs of 75 meter SSB transceivers built around FT-241 crystals. No more complex to build than an HBR receiver. One of these days I may actually build one just for the heck of it.

Point is, it used to be so much more common than today.
>
>I think the "parts shortage" is exaggerated.

I'm old enough to recall a time when you could order almost any part a ham could want from Newark or Allied - if the local radio parts emporium didn't have it. Outfits like G&G and Fair Radio sold surplus at lowlowlow prices, and postage was cheap. Most big cities had their Radio Row - Philly had Arch Street, and NYC had Cortlandt Street. All gone.

The parts shortage started in the early '70s, as many outfits went out of business, dropped ham-type parts from their stock, and/or required high minimum orders.

Today the situation is much improved, in large part due to the 'net. Instead of paper catalogs, we have websites like Mouser and Digi-Key.

True fact: Digi-Key got its name and its start back about 1968 by selling RTL digital logic ICs to hams for keyers. Look for their tiny ads in the back of the QSTs of the late '60s and early '70s.

>As for the oft cited
>time crunch of modern life, I think this is sometimes used as an
>excuse by guys who for some reason feel uncomfortable about all the
>appliances in theirs shack.

It's real, but in ways that are not too obvious. See below.

>One ham I know ALWAYS says "I wish I had
>the time," when homebrewing comes up. He's an avid golfer.)

Consider this: If he goes to play golf, he's guaranteed at least a few hours of uninterrupted fun, either by himslef or with like-minded buddies. He may have difficulty getting an equivalent amount of uninterrupted time in the home workshop. Between the honeydew list and the telephone, golf may be all that keeps him sane.

>I'm sure
>this IS a problem for many people, but there seems to be plenty of
>time for CONTESTS!

I build my own rigs and contest with them. See QST for June, 1994, page 55.

>And aren't we always being reminded of the high
>percentage of retirees in our ranks. Parts shortage? Time crunch?
>Lets face it, most hams just don't like to homebrew. To each his own.
>More parts for us!

>
Here are some other factors:

- lack of space for a proper workshop and parts storage
- less than perfect eyesight and fine-motor skills
- lack of resolve/desire/drive to start out with simple projects and work up to advanced stuff.
- lack of examples (you'd be amazed how many hams, upon visiting my shack, remarked that they had NEVER seen a 100% homebrew ham station.)

You might try these

http://www.linxtechnologies.com/

You don't need a license unless you use an amplifier and then you only need
apply for a business license, similar to a CB license. At least that is the gist
I go from the company when I needed some of their transmitters. Any one here
know the exact legalities of these tx/rx's?

I have been a member more than not over the years but decided against lifetime membership back when it was actually a bargain because I decided it was very much a possibility that some boneheaded move made by the BOD would cause me to drop out -that happened when they sued the FCC over the 220 mc band that was a real boneheaded stunt IMO. I signed on again in a few years but came very close to dropping again last April when the time came around. I finally decided to go for another limited term since I do believe we really do need a strong representative in DC and elsewhere. But the right to dump them is reserved.

>objective is to sell as many publications as possible. If that means

When I said something very similar to your comment on .policy a few years ago a staffer really dressed me down for even suggesting such a thing!

> Is it in the best
> interest of ham radio to do so? I don't think so.

It's a plan to maximize the take. Not that a good cash cache isn't needed, but it dilutes hell out of QST and makes it much more difficult for beginners to get and stay current. I have never subscribed to QEX on principle alone - from the start it was clear that the main intent was to sell everyone another subscription - and I know I've missed a lot because of it. I also no longer buy new handbooks. Back when they were priced as though they intended for one to be in every ham's library, I bought a new one every year. Now I get them when they're a few years old - someone is always selling last years issue, or earlier, still new, at hamfests for a fraction of retail. I know some other OTs with similar feelings.

The intent seems to be to integrate all the "hobby" radio services into some umbrella sort of organization. That was the subject of a QST editorial some time back. Bring in all the sheep into the fold, and get their $$$.

It's a different world and it ain't ever going back.

Yes, but the main attraction for most of us was

GET RID OF ALL THOSE #$@~!%^$# HETERODYNES!

If you were around listening to 75 meter SSB in the late 50's-early 60's you know what I'm speaking of. DSB would have done that, too, with much simpler gear.

You can make an equivalent mixer with two small ferrite core transformers and four diodes. For HF, ordinary silicon signal diodes do as well as hot carrier diodes in nearly all cases, although a little more LO power is required. Two places I know of where there's a schematic are _Solid State Design for the Radio Amateur_, and "An Optimized QRP Transceiver" in August 1980 _QST_. I'm sure you can find a schematic many other places. Look for "double (or doubly) balanced mixers" or "diode ring mixers".

Anyone seriously or even casually interested in commercial applications
of unlicensed transmitters in the U.S. should get and read a copy of
part 15 of the FCC rules. It's just a few dollars from the Government
Printing Office, and the real answers are all there.

2692. Re: Local Oscillator Waveforms

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-29 06:10:19 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D96994B.10201@eznec.com>
Source record: 41055

An oscillator is an amplifier with feedback and a loop gain greater than one. This means that the oscillation will build up, and up, until something limits it. The more gain the loop has, the faster the oscillator will start, and the more leeway you have for component tolerance, temperature variation, etc., but the more severe the limiting is. This limiting usually shows up as flat topping of the waveform. So the raw output of most oscillators isn't very clean. (Getting control of the limiting process is one secret to making stable and relatively clean oscillators.) The obvious solution is to run the output through a filter. And it helps to have a resonant circuit of reasonable Q as part of the oscillator, and get the output from that tuned circuit, loading it as lightly as possible.

But the fact is that the ideal LO signal for diode and most other types of mixers isn't a sine wave anyway -- it's a square wave. LO harmonics don't necessarily translate to poor mixer performance. But you do want the waveform to be symmetrical, so the resulting switching takes place at regular intervals. Generally, the easiest way to do this is to tap off the oscillator at a relatively clean point, run the signal through a lowpass filter, and amplify as necessary. The Wein bridge approach is another solution, but not one that's usually used.

Roy Lewallen, W7EL

Hi all,

I'm interested in building a Amplifier capable of the legal limit here in
the UK of 400w, I would like it to do this comfortably but at minimul cost.
Are there any good Amp Projects on the web?
Any idea where to get HV Transformers from here in the UK?
Any good suppliers of HV Variable Capacitors and accessories?
Any good suppliers of used Valves?

Thanks for any help.

Kind Regards,

Jim M0CKE

.
.
Thats right it will, of course it won't die completely, just like we
have guys that repair steam engines etc
But it will become a very rare hobby, the componant issue will be
a major concern, much of homebrew will become a search for
componants as everything will just be an irrepairable module, you
can see how its going, have a look at the latest computer boards
and mobile phones, size will be another problem, you just won't be
able to hande the componants unless you have the skills of a
watchmaker.
As for time well unless you are retired you just won't have it, thats
a sad fact of life these days, leisure time is TV DVD or something
physical to keep in shape like Golf etc
And lets face it it's difficult you have to have the knowledge to do
it, which means learning something, and very few young people
today want to do that, they want instant results.
of course old homebrew diehards will carry on but when they are
gone that will be it.....

Why do people insist on posting where/how/what to buy the commercial equivalent of what you can build to a news group labeled *.homebrew? If we wanted to know what to buy off the shelf we'd pick up the latest ham rag, not post to a news group specializing in building things. We need less appliance opperators giving advice in this news group, maybe some people might take some enjoyment out of building something that can be bought for less. Wait a minute, we just might learn something in the process...Oh the humanity.

Here's a nice charger project:
http://www.gnt.ee/users/ergo/charger/index.html

Have fun, and happy home-brewing!

I use 3 strands of fine wire and twist them together with a bolt
hanging from the bottom. Twist up a length that will go thru the core
7 or 8 times..I have used ferrite beads salvaged from old tv's for the
cores, and 1n914 diodes. They can be made very small if you mount them
smc-style. Also there are several articles about this in ARRL'S QRP
Classics.

Right you are, Dick. I forgot all about the heterodyne problems. Most good rx's
of those days had notch filters, but they could only deal with one heterodyne.

Yup. And there were some DSB rigs built by manufacturers. The WRL SB-175, for
example.

I'd like to trade a plug-in Collins AM filter for the 75S-3B
or 75S-3C for either of the following for the 75A4:

* AM filter, 6 kc
* CW filter 500 cycle

Look at filter information for some pictures and my e-mail
contact information.

If you prefer:

For the software inclined, Atmel's Tiny-26 processor makes a very nice
battery charger.
Switchmode, with current, voltage, and temperature sensing. You need to
provide the power electronics, a few Rs and Cs, but it's on-chip high speed
PWM is brilliant.

2706. Re: Homebrew in QST

Another big advantage of the DB rigs (and what got us started in this thread): simplicity. I agree that a simple SSB TX is not much more complicated than a DSB TX. Sort of like the difference between a DC receiver and a simple superhet.

But when we start talking about TRANSCEIVERS, DSB simplicity becomes a real advantage. I think it is significantly easier to build a DSB transceiver than it is to build an SSB transceiver.

DSB transceivers might represent an oppotunity for new hams to build their own phone rigs. And these rigs would be MUCH cheaper than commercial gear. I think a phone rig would be more attractive to the younger generation than a CW rig.

There are some interesting DSB rigs out there: From Cuba come stories of the fabled "Islander" transceiver, a hybrid tube/transistor DSB rig built from old Russian TV sets by intrepid youngsters. From British Columbia there's the "WeeWilly" by Dick Pattinson, VE7GC. From Sweeden we hear of Johan Bodin, SM6LKM's "Optimist" 80 meter DSB rig From Japan, Kazuhiro Sunamura, JF1OZL's huge web site contains a number of very nice DSB rigs. And from down under, Peter Parker, VK3YE's web site sings the praises of DSB. The G-QRP club's quarterly SPRATcarried reports of Eric Sears' legendary ZL2BMI DSB rig.

Ask this in sci.electronics.repair. I don't know of a source in general
for pinouts, but if you can identify the maker, or the TV it came from,
you might be able to track it down.

Actually what we need is a DSB rig with an autotracking DSP selectable sideband filter just ahead of the driver..... :-)

>[stuff deleted]

But I think this is cheating. You seem to be talking about a receiver
that can't receive DSBsc.

One reason that DSBsc took off for a while in ham circles was because
SSB was already moving in, and so receivers started getting narrow enough
to pass only 1 sideband. So a DSBsc transmitter worked because it
was turned into an SSB signal in the receiver.

If you didn't have that selectivity, DSB was problematic. You'd have
the problem of getting the reinserted carrier exactly in the middle
between the two sidebands. With SSB (or DSB converted to SSB in
the receiver), if you were mistuned you'd simply get a wrong pitch.
If you try that with a DSBsc signal, when you translate the sidebands
down to audio, they won't land on the same frequency. And that will
be far more disturbing than a slightly mistuned SSB signal.

DSB, unless you do that receiver-end conversion to SSB, requires
a fancier detector, one that will lock the bfo to that exact spot
between the sidebands. And if you get fancy enough with the detector,
you will receive the advantages of sending the redundant sideband.

Since you are talking simple, I suspect you are thinking of a
direct conversion receiver. This will be troublesome at the very
least when receiving DSBsc. Such a transceiver would count on
the other guy transmitting real SSB. But to propose this as a popular
approach implies that the other guy may be sending DSBsc as well.

Yes, you could go to a phasing direct conversion receiver, but that
boosts complexity. Or go to a superhet with an SSB-bandwidth filter,
again a move to more complexity. And in both cases, once you start

going there, much of an SSB transmitter is in place. So what's the advantage of a DSB transmitter at that point?

What is advantageous about DSBsc transmitters is that you don't have to worry about a conversion from a fixed frequency where the sideband filter resides. But that signal-frequency operation loses in a transceiver if you've got a superhet, because you can't use the same local oscillator for transmit and receive, unless you add more complexity to the circuit.

In the days when DSBsc transmitters were relatively common, a lot of hams were still using separate transmitters and receivers. The average transmitter used a VFO on the signal frequency (or a subharmonic of it), and one could convert an AAM transmitter to DSB with a bit of work, or use a CW transmitter to drive a high level balanced modulator. This added to the usefulness of the scheme.

Now, when most people use transceivers, they would expect real transceive, and the the simplicity factor is less of an advantage.

One important thing to note is that when generating an SSB signal, you have a controlled situation, unlike in a receiver. You can use a relatively wide crystal filter, because you have the luxury of using audio filters to limit bandwidth. Since you can control what goes into the balanced modulator, the filter doesn't have to be too exacting. It's the same thing with phasing, too; that phasing network can be simpler because it is handling a limited audio spectrum. Filter the audio carefully, even just use a microphone with limited bandwidth, and all you have to be sure of is that the IF filter (or phasing network) knocks out the opposite sideband. Try it on receive, and a strong adjacent signal will get past the lousy filter.

Michael: Yes, I am talking about using a simple DC receiver, and you
are right about the problems that DC receivers have in handling DSBsc
sigs. But here is where all those appliances come in handy! Our
intrepid young radio builders will have no problem finding
Yaesucomwood ops to talk to. They just won't be able to talk (without
distortion) to other intrepid DSBsc homebrewers.

Unfortunately this wouldn't be much of a problem. I ran a DSB rig on
17 meters for about a year. One day a guy asked me what I would do if
I came across another similar rig. I told him that this was not
something to worry about. I never did run into another DSBsc rig. I
don't think I've ever worked one in all my years of hamming.

Another benefit of DSBsc rigs: the fun you have in explaining things
to guys who try to tell you you are on the "wrong" sideband.

Hi
just some ideas:
A) modify an old CB amplifire for HF bands
B) use russian tube
C) use the HV transformer of home "microwave furnace" (is it the right
word?)

of course you can do A+B+C;
ciao

PCB is great for making boxes, I use it a lot see
http://www.hanssummers.com/radio/cwtx/index.htm and
http://www.hanssummers.com/radio/polyphase/index.htm. Brass shim isn't as
sturdy, I don't think it's as easy to solder, and it's probably more
expensive too...

2720. Re: About AF derived AGC

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-09-30 13:14:32 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <an9ino$ceed6$1@ID-61331.news.dfncis.de>
Source record: 41083

Thanks for the discussion, I have learnt a lot more about AGC.

I said "relatively constant" because I thought in practise "constant" isn't likely to be possible. I now see why one wouldn't always want truely constant output e.g. you don't want huge noise level when there is no signal.

In my design I have no RF amplifier, just the FST3253 switching mixer. This operates on a +5V supply and the incoming signal is biased to midpoint so I think a 4V p-p signal would be switched without problems. Following the mixer is 33dB of amplification before the phase shift network, these are NE5534 op-amps on a 12V single-rail supply, so perhaps 10V p-p signal coming out of those before clipping - which means 227mV p-p. So I should be able to tolerate something like a 200mV input without overloading, right? What is considered a maximum level that a receiver should be able to handle?

Ok, so what I will build is an AGC system having a variable "delay" threshold below which it does not operate. Adjustable attack and hang times. And adjustable depth of AGC to control how "relatively" constant the audio output is (slope of the out dB vs in dB curve). I am planning on using the CA3086 transconductance opamp similar to my use of LM13700 here http://www.hanssummers.com/electronics/equipment/muscle/index.htm which was very effective.

Thanks for all the answers

The diode to ground configuration is noted in the 2002 edition of the
Radio Amateur's Handbook (see page 14.15, top left column) as a source
of phase noise.

I'm curious as to why there is so much concern over the wave form of
the oscillator. It seems to me that the real concerns for a circuit
like this ought to be stability, phase noise, and durability.

Perhaps you'd get better results by asking in the correct
newsgroup.

Read the name of this group again: rec.RADIO.AMATEUR.homebrew.
In that context, 'homebrew' refers to the design and construction of
self-designed electronic equipment specific to the hobby of amateur
radio.

rec.crafts.brewing
rec.food.drink.beer
alt.brewing

are more specific newsgroups for your question.

Wine and beer hobby stores often have an introductory kit that makes
roughly one gallon, as well as books on how-to. Not all that
complicated with modern stuff and kitted ingredients, as long as you
can follow directions well.

Many do home brewing more for taste than for saving money, but
typically you can end up with premium beer taste for generic beer
prices.

Depends on type but a week or two minimum from starting. Can't rush
fermentation.

Since the local oscillator feeds a mixer which generates a whole set of frequencies as well as the wanted fin-LO, I would have though having 2nd, 3rd or whatever harmonics would probably be a bad thing as they would all mix in wierd and complicated ways with all the other mixing products?

This radio uses a simple dual gate MOSFET as a mixer.

I assumed that a sine wave from the LO would be the best possible input to this mixer. Are you saying that a square wave would be better?

I was also wondering what difference the signal level injected from the LO made?

BTW the current oscillator is a basic Reinartz LC oscillator. The waveform is really really bad with some high frequency "ringing", possibly the resonance of one of the two smaller windings?

regards...

You will almost certainly have filtering in the front end of the receiver.
You should probably have a filter (bandpass or low pass) after the LO if the
mixer is linear . If you look at the waveform at the output of this it will
look like a good sinewave. If there is ringing in the waveform it could be a
harmonic or maybe a parasitic oscillation at a higher frequency. If you had
a spectrum analyser it would easy to see :)

>products?

That is of course true for most switching type mixers. With a
symmetrical square wave there are quite strong mixing products with
the 3rd, 5th etc. LO harmonics.

However, in an up-conversion receiver, the LO is quite high in
frequency and thus easier to filter out. With an IF of 45 MHz and
0-30 MHz tuning range, the LO range is 45 - 75 MHz, the 3rd harmonic
at 135 - 225 MHz and the first harmful spurious responses come from 90
- 180 MHz, thus quite easy to filter out with a 30 MHz LPF at the
front end.

>This radio uses a simple dual gate MOSFET as a mixer.

And if the LO also has an asymmetric waveform, there are going to be
strong 2nd harmonic response. The situation even gets worse, when down
conversion is used and the LO is below the RF. Assuming 4 MHz IF and
receiving the 14 MHz band, the LO is at 10 MHz, the 2nd harmonic at 20
MHz and the first spurious response at 16 MHz. Thus, the front end
filter should pass the 14 MHz signal, but strongly attenuate the 16
MHz signal.

Anyway, using tunable front end filter or at least fixed band pass
filters for the amateur bands only, is a good thing to reduce mixing
products with the LO harmonics, but also to reduce RF 3rd order
intermodulation products ofincomming signals and to reduce reciprocal
mixing with the LO phase noise.

A linear mixer ?? If two signals are passed by an absolutely linear circuit, they appear unchanged on the output and no combinations of them are obtained. Mixing two signals is by its nature always a non-linear process. A mixer MUST be non-linear, having either a curved or "part-by-part nearly linear" folded characteristic. If the latter is the case, the operational point must swing across at least one of the folding points.
A single tuned circuit with moderate Q should be enough on the oscillator output.

PSE excuse my lack of proper English terms.

Depends on costing - I got squre metre pieces (nice fibreglass double sided) at the local trash and treasure for virtually nothing, so I use it for boxes. Brass shim costs a fortune by comparison!

Probably not - as has been pointed out the same technology that brings us the $150 colour television now brings us the relatively cheap ham gear - and like TV and VCR (and indeed all consumer equipment) its so loaded with "features" that homebrew cant compete. The "features" may be irrelevant but, hey, its in software so its cheap to introduce.

The 50's and 60's are gone, no more nice WW2 surplus to provide us with beautiful mechanical drives and cheap parts (although, we never think of the price our world had to pay to get these things) so its time to move on to modern techniques and methods.

SMD is a pain, but so was learning Morse or the theory needed to pass the ham exams, even a cursory(sp) web search will bring up dozens of tutorials on how to use it at home - sure, you might need to buy a pair of magnifying specs (mine cost me $3 for x3 magnification), a decent high intensity desk lamp ($10 in Kmart) and 2 cheap soldering irons to remove components from boards. And if you want to remove the big smd chips, WELLER (among others) make a neat little gas catalytic burner thats ideal for this task. Sure, it takes practice and perseverance to get competant, but then so did 20wpm CW.

Many people in this thread have replied with examples of superb home brewing using modern components, doing things that were unheard of 30 years ago. A digital readout for your receiver - 1 PIC micro, a LCD display, and a power line - what could be easier? - at one fell swoop,

all the old VFO problems are largely solved - so if the VFO drifts, you can see it on the display and bring it back! - can you imagine a 50's VFO that somehow mechanically tracked the VFO scale to oscillator drift - I think not.

What we need is to use lateral thinking - there is a hell of a lot of surplus modern junk that can provide some nice bits for home brewing, eg trashed cellular phones have all sorts of nice front end/mixer/synthesiser chips in them, computer power supplies can be readily reworked to give 12v at 20 amps plus, and in a box that sits at the back of the bench and weighs only a pound - how much does a 20amp linear supply weigh? - the cost is about the same because, lets face it, as Amateurs we are cheap and wouldnt dream of actually BUYING the power transformer and filter caps!

Surplus uwave TV signal downconverters can be readily modified to hear AO40 on 2.4GHZ - like, how good is that - for the time to salvage one from a neighbours roof and a bit of hacking, you have something that even in your wildest dreams you couldnt home brew in 1950!

Its easy to get nostalgic about the good old days (I remember them too, you froze in winter because only the rich had decent heating, if you were lucky you had a clapped out old car, the food was lousy because it was all we could afford, we had lovely diseases like polio, smallpox, ricketts ,malnutrition, social events like the cold war (and hot ones as well) and most of your time was taken up with survival, not leasure pursuits)

I think it says in the ARRL Handbook "The amateur is progressive" - it still holds true, we will adapt and prosper and do things the old timers could only dream about if we only stop saying "ITS TOO HARD, WE WILL GIVE UP!"

Maybe the problem is that in his local currency the SBL1 would cost a
significan part of a weeks wages - we cant all live in (or next to)
the USA with the assosciated standard of living and disposable income.

Couldnt copper tubing in some tank coils be used in a still?

2742. Homebrewers lies swapping Octoberfest in NY/NJ/PA

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-01 14:57:40 UTC
From: k3bu@aol.com
Message-ID: <20021001105740.05495.00010982@mb-fc.aol.com>
Source record: 41005

Come and have radio-octoberfest fun!
Even if it rains!

You are all invited to (Radio) "Uktoberfest" at Mountainview Resort Verkhovyna (dance hall) in Glen Spey, NY (NY, NJ, PA tri-state area) hosted by the Tesla Radioclub and Ukrainian-American Cultural Foundation - UACF on Saturday, October 5, 2002, starting at 3:00 pm till ???

Come and have fun meeting other hams, DXers, contesters, while having good time and drinking Spaten Oktoberfest and Ukrainian Obolon beer. Enjoy Ukrainian food (special kobassy/wurst, kapusta/sauerkraut, pyrohy/pirogi, sweets) and German food (sauerbraten, spatzel, red cabbage, apple strudel), listen or dance to endless polka's by Czornozem live band and DJ Yurko-Durko. Wear your badge, hat or shirt with callsign proud and meet other radio aficionados around the "radio" table reserved for hams. Free admission to Hams, firemen, police officers, just show your badge.

142 acre Verkhovyna - MountainView Resort is the new home to Tesla Radioclub N2EE station.
Join the semiserious discussion of how many towers do we need to put up there. Come, check it out, join the club and get a free beer. Bring your family and friends.

Directions:
Take Hwy. 84 to Port Jervis, NY exit 1; follow Rt. 6 through Port Jervis to traffic light with Rt. 97/42 signs, go through and follow Rt. 97 west for 10.8 miles to Pond Eddy ("Nolan's" motel on right, bridge on left), turn right onto High Rd. (Rt. 41), go up the steep hill for 1.7 miles, Verkhovyna is on the left.
Plenty of parking.

More info, maps and satellite view of the resort are at www.Verkhovyna.com home page under directions.

See you all there and join us yodeling in Morse code :-)

Nazdorovya, Ein Prosit!

For more info contact
Yuri, K3BU, tel 973 808 1970 Email K3BU@aol.com
pres. Tesla Radioclub, host of Uktoberfest

>Couldnt copper tubing in some tank coils be used in a still?

He said BEER. You don't need a still for beer. :-) I used to cook hot dogs in the tank coil of my old 40 meter transmitter.

Unfortunately, there aren't any vacuum-tube devices that work as heat pumps, but there is a solid state device - the Peltier(sp) junction. The trick would be to incorporate these devices in a manner useful for something, besides cooling your beer. I actually had a beer spigot on an old power supply, but it was just for looks.

Really nice capacitor bank with board and eq resistors already
mounted.
It has the screw type filter capacitors. They are mounted on a
commercial made PC board with eq. resistors. It consist of 15 -
1500mfd @ 450vdc
computer grade capacitors in series. There is room for one more cap,
of
which I have a couple of spares 17 total caps. There are also some
extra resistors mounted on the board you could use to add the last
one.
That would give 93 mf at 7200wvdc. That is nothing to sneeze at! Most
of the HARD work is already done for you.
Great for your next high powered project. It will fit in a standard
19" rackmount chassis it is 6" tall 9 3/4" depth
Figure about 25lbs packed weight shipped from 28681 would like 100.00
+ shipping open to offers I could use 2 oil capacitors around 20mfd @
5000vdc each Ok if cap is higher.ni4l@charter.net

Message-ID: <3200347.0210010929.514d5163@posting.google.com>
Source record: 41009

As Roy suggested, if you couple your tank circuit lightly to the active element, you can get lower distortion output. But you can also (read: in addition) pick the output off a relatively low-distortion point in the oscillator circuit. If the tank is high Q, then it's going to have low harmonic content, even though the waveform at the oscillator transistor (or other active element) may be full of harmonics and very spikey. So...you can connect a low-distortion amplifier to the tank and get low distortion that way. Be sure the amplifier is low noise (so it doesn't add a lot of phase noise) and doesn't load the tank (so the Q remains high). You can find some examples of this sort of thing in the ARRL literature, I think.

In an ideal product detector/mixer, where the output is input A times input B (in the time domain), then the ideal LO waveform will be a sinewave, to minimize response to harmonics. Most mixers don't have such a simple relationship. And certainly you want some filtering on the input and output signals, so you select the mixing products you want and don't care that much about responses at LO harmonics. In the broadband spectral analysis equipment we build here, we generally try to excite the LO port of mixers with single frequencies (even though they will still have a strong response at odd harmonics of the LO), and may put diplexer-type filters between the LO amplifier and the mixer input...the diplexer to keep loading on the LO port at a constant value over a wide frequency range.

Cheers,
Tom

Sounds wonderful, and you have sold it to me, but then I'm a Hb'er
myself
But if you think the average youngster is going to sit for hours with
a magnifier trying to sweat componants from an old phone, then you
are out of touch with the younger generation, they simply don't want
to know, they have grown up in a different world where they are
consumers, they buy, and if they can't buy it then they are simply
not interested, its a fact......
And without youngsters HB has no future.

My apology. I was thinking in terms of diode ring or other switching mixers. The dual-gate mosfet mixer can be categorized as a square-law mixer, and for that a clean sine wave should be used. The general procedure for getting a good sine wave is to reduce the oscillator loop gain to the lowest possible value that still gives reliable starting and running (to reduce the amount of limiting as much as possible), then run the output through a bandpass or lowpass filter, buffering if necessary.

The high frequency ringing certainly doesn't belong. This could occur with some topologies if the active device is allowed to shut off during the cycle (allowing a combination of inductors and capacitors to ring at their natural frequency). Or it could be due to unintended parasitics. It shouldn't be there, and you should fix it. Lowering the loop gain might help, or you might go to a different oscillator topology.

There's a very good discussion of both oscillators and mixers in Hayward's _Introduction to Radio Frequency Design_, available from the ARRL.

I do homebrew with SMD parts down to 0402. I used my standard weller iron for years, but recently retired it for a Metcal, and a toaster-oven. A little paste, a little flux ,and 15 minutes at 450. :)

I'm 44, with failing near vision as well.

Same here. 1x2 ft double clad boards were $1. Couldn't go wrong.
Jigged them up on a piece of pine, little flux, nice hot iron - bing!

Gary

Have the people that want the 6MHz chunk ever heard of 'spread spectrum' ?
They could easily design an adaptive, broadband radar waveform for their
(fleet of) satellite(s) that would be virtually immune to interference and
would also have a very low probability of detection. The technologies are
pretty much off-the-shelf. And why limit themselves to 6MHz ? Take the
full 50 MHz (or more) for their spread spectrum signal.

In other words, the required bandwidth could be shared. There is no need
for anyone to move off of the band. All they need is a secondary or
tertiary or etc. asignment for their little project.

BTW, in the depths of the Amazon (for example), I wonder how many users of
70-cm band Ham radio equipment are licensed Amateur Radio Operators ?
People in the less developed countries tend to use cheap Ham equipment (and
frequencies) for all sorts of purposes. Good luck getting them to QRT...

True, you got me there - which Germany do you mean, the economically
prosperous West or the basket case East - and yes, I know they have
been reunited, but the economic differences remain. And what is his
social/economic status in his society - and perhaps, too, he doesnt
want to buy a pre made mixer but would rather homebrew.

Sorry, have to disagree with you on two counts, (and I am generalising like hell here, so can be asily shot down in flames) vis

1. The people who cant be bothered trying SMD/new techniques/home brewing are the same ones who couldnt be bothered playing with valves back in the fifties, so the attitudes of youngsters havent changed!
2. its not so much youngsters who are coming into the hobby, its the retirees who after a lifetime of work are now able to sit down, do the exams, and take up AR, and probably had always wanted to since they were kids!

I think AR is unique in that it is a "hard" hobby - you need to sit an exam before you are allowed to pursue it. We do it because its hard, not because its easy. 30 years ago I was lucky enough to be mentored by my "Elmer" (Ross VK1AN) and I have always remembered the time and effort he put into what must have been a sometimes annoying and frustrating task. I am eternally gratefull to him, his tutorials and sharing of knowledge and attitude were the basis of my lifelong career. In the past 30 years I have been able to do this for ONE newcomer, and he is doing really well - in 3rd year at university, and so knows heaps more than I ever will. But he has the Ham ethos, he scrounges, goes to junk sales, goes through the hard rubbish piles on the sidewalk - the difference is he is quite comfortable with SMD, Uprocessors, - because he grew up in a time when they were taken for granted.

Most of us can remember the time when we were kids (before we were hams,) and the commonality is the "how does it work, cant I fix it, can I take it to pieces" mindset" - where else can you go besides AR if you feel like that (And yes, there are probably heaps of areas you can get mildly obsessive about, I know...) AR has ALWAYS been a minority hobby for the technically inclined, and will attract the sort

of people who want to muck around with electronics and build things - for most of them, they only get on the air to try out a new piece of gear or to test new mods etc - the rest of the time they are busy building/scrounging/improvising etc.

In Australia we call it "Have a go" - this means, try it out, you might stuff it up, you might succeed, in any event you will have tried.

Except that the news server is a commonly used, good quality news server, which can be used when you just register to it, thus, it is commonly used by people whose own ISP does not provide a decent news server.

Thus, you should not draw too much conclusions about where the original poster is.

Why should a distributor in country X stock such exotic components as the SBL-1, if there is not any local industry using such components or it is needed by a radio repair shop. Ordering components abroad can be very expensive and time consuming due to the bureaucracy in some countries. Within EU and between USA and Canada, such bureaucracy has greatly been reduced, but can be quite common in other parts of the world.

Fortunately the SBL-1 can quite readily be replaced with four signal diodes 1N914/1N4148 and two transformers made of two ferrite cores and some wire.

.

Well you will probably hate me for this but it has to be said
Australia is about where the UK was about two years ago
as regards PMR and general thinking amateur radio wise
PMR is nearly over with in the UK its all going cellular or
broadband, during my last year as a comms engineer in the
UK we were told not to refer to the mobiles as radios but as
mobile interfaces, and that is the thinking, the actual transmit
function of these "interfaces" is treated as just a platform for
the interface to work through, its a different way of looking at
things, and this I'm sure will carry through to how communication
will be looked at in the future, in fact it already is here, the old
magic of some guy surrounded by dials and knobs pushing a
morse key and talking to some other guy in the rain forest of
central Africa is gone forever, youngsters just don't see it that
way, as far as they are concerned if you want to speak to
someone at a distance you reach in your pocket and get your
phone out, and they are not the slightest bit interested in how
it works, a bit like the average lady driving a car :)
And that goes right through to electronics as well, if its difficult
forget it is the general thinking, its not a bad thing, just a
different concept, we will enjoy electronics to the bitter end I'm
sure as we still see the magic of it, but its doomed as a hobby
for the future.....

You miss the point. 432 MHz is NOT an amateur band, and never
has been, at least in Region 1.

UK amateurs use it on sufferance from the MOD (apparently).

Look up its status.

Well said Andrew!

Ham radio never has (and probably never WILL) appealed to more than a fraction of a percent of the population. It is fueled by a general curiosity about things technical. I've been amazed by the number of people in the local ham community that are also the "movers and shakers" of the local experimental aircraft community! You can get in any random group of hams and find someone to talk to about space, model rockets, robotics and just about anything else "too technical" for your average man. To such a group, the "hardship" of SMD work becomes more of a "challenge" and may actually increase the appeal. I've recently found myself becoming more intrested in things "microwave" and am finding that the plethora of SMD devices make it much easier than in years past.

Another thing I'd like to run past the group: Is it just my imagination or is there really a STRONG inverse correlation between active ham communities and the size of the "general population" community? It seems that the least active (and least friendly!) communities I've been in are those in large cities. Conversely, ham groups in small towns seem to be more active and ready to say "Hi" to a new call.

Well it looks as though Quecan of Canada is going to try to shaft me on the Sunair GSB-900SC I purchased from them through Ebay.

I paid almost 500.00 for it plus 100.00 shipping. Upon arrival I found that there were problems in the power supply, It had a bad microphone, the power cord was missing, and that nine printed circuit boards were removed and missing.

I attempted to contact them and they avoided me for a couple of days. When they finally did I contact me I was told that it was sold AS-IS and I was stuck with it. I tried to get them to agree in either a partial or full refund or even to just send the boards. So far they have refused to try and correct the situation in any way.

While I can repair the problems in the power supply and even replace the mike cord, I do expect that the radio be complete.

Can I get any of my fellow green radio collectors to contact them and help get this resolved.

The contact person is Christiane Boplduc
813 St-Jacques
St-Jean-sur-Richelieu,
Quebec J3B 2N2

Telephone 450 346-7460
Fax 450 346-7638
Email quecan@qc.aira.com

Any help would be greatly appreciated. Thanks Don Smith KB6GQA

OK, so getting back to the original topic, the SBL1 can be pretty equivalently replaced by 4 diodes and 2 transformers. For HF, the transformers are commonly made from ferrite toroids, the exact size and mix being somewhat dependent on frequency.

Take a look at Jim Kortge's 2N2/40 page (http://www.qsl.net/k8iqy) for lots of examples. This basically is pretty standard fare. It isn't at all unusual to use this approach rather than the SBL. The SBL is a dandy performer, but a few minutes spent winding a couple of transformers will produce a mixer almost as good.

Hello Erik!

There are no ready to use equipment which like plug and play available.
This need to build a test assembly.
One method is to use a signal source and a VSWR bridge and another more
expensive to use a network analyser. Some of them works from 10 kHz.
Actually could find a VSWR bridge from 40 kHz.

Well the whole point of this argument is being lost, I agree with all thats said here, smd's are fun, I still enjoy home brew as much as I always did, so obviously does everyone contributing here, BUT when we are gone it will be no more, simply as I keep saying there are very few yougsters doing it!!!!
Not sure about the community bit, I remember as a child we knew everyone in our street and what they did, these days I know my neighbours two doors either way and across the road and thats it! people don't seem to want to talk much these days, they say "Hello" but don't let you into their lives, now what would be interesting would be a survey of the ages of Amateur radio group members and electronics clubs, the RSGB must have a good idea about their membership, and thats probably the reason for all these licence changes that seem to be upsetting quite a few, perhaps they see themselves out of a job in a few years hi!!

With respect, gentlemen, I suggest that you missed a major development that suggests this argument misses the point. The point is, like everything else, amateur radio changes. Observe what is going on. The youngsters ARE there and they ARE licensed. You just don't see them in your particular spheres of interest.

With the advent of cheap (relatively speaking) computers and their associated sound cards etc, there has been a tremendous jump in the amount amateur radio-based software. New digital modes have been invented and have taken over the traditional RTTY segements (execpt on RTTY contests). Logging programs that rival commercial database management systems are common. The bulk of this software is FREEWARE with SHAREWARE a very close second. In fact, just last night, I realized that 75% of the programs I run on my home PC are freeware ham programs. Not counting Windows (shudder!!), 95% of my software was programmed by hams.

The "kids" are into software development, digital communications, and computer-based ham operations (xcvr control) with a vengance. What they are producing is top of the line, user friendly (take THAT Microsoft!) nearly bug free ham software for the sheer joy of it, it would seem. Why else would so much first class software be freeware?

Things change; ham radio changes.
"Think of it as evolution in action!" Larry Niven

Will Webster
WB2TNC
(Who can't wait to see what the "kids" come up with next!)

> for the future.....

Soory, it really means a wonderful opportunity (gee, I sound like
Pollyanna here) - trunk radio has happened here, and suddenly there
were literally truckloads of used VHF and UHF commercila radios for
scrap metal prices - I got a Philips FM900 for $30, a fellow club
member converted it for another $30 (he had the Philips programmer and
an IFR) and so I now have a good quality 100 channel 2m radio for the
work vehicle - and it wont worry me too much if it gets knocked off,
but I would be really cranky if a Yaesu/Kenwood?Icom mega dollar
transceiver went!

A few months later, the same thing happened with UHF AWA RT85, same
procedure, so now I have 2m and 70cm mbile for virtually nothing ! if
we as amateurs cant see golden opportunities from new technology then
there is something wrong!

There is hepas of commercial UHF and uwave stuff out there at give
away prices, most of it readily adaptable to amateur use - If I cantr

figure out how to do it, someone else will, and spread the message via this medium, a wonderful piece of technology we are having this discussion on. Its 11pm at night after a long day, and I can sit down, relax, and have a good QSO via the keyboard - sure, its not real time, but it beats the hell out of 45 baud RTTY on HF, and I dont miss having to fix the Model 15 teletype every few weeks!

And I love my "Whitegoods" car - I get it serviced 3 times a year, dont even need to check the oil, just put petrol init. And it doesnt leak oil all over the driveway (dont know if Pommy engineering has mastered thsi one yet hi hi) and I dont need to spent every weekend doing "routine" maintenance.

Nothing has changed, and fathers and grandfathers did the same, they looked around to see what was available and how can we hack it to amateur use.

Saw a wonderful piece of lateral thinking on thsi medium the other night, some bloke (forget the call) had worked out that a TV tuner from the tip made a wonderful 6m preamp for his converted CB - varacter tuning on input and output so its fairly sharp, tuneable via a pot and 12v, disanbled the LO by cutting out the osc. coil - and voila, a hot 6m preamp for a visit to the tip!

We will survive, we will prosper, we will go on to bigger and better and probably more looney projects as the years go by, and I honestly think (as mentioned in this discussion) that there will always be a small group of people who love to tinker, to adapt, and just plain muck around with technolgy!

Harvey,what about the people you are yacking to in this discussion - I dont know my neighbours (I dont really want to, they dont have any test equipmet I can borrow) - this is our new community, the spread of technology has enabled us to do this - I probably would never have heard you on HF, and it would most likely have been "59 QSL via bureau" if we had! - dont be too down, its a changing world (as its always been) and we will change with it, new techniques, new modes of communications, new amateurs to ragchew with -what could be nicer than that!

Are you sure you need an SWR meter ?

If you want something to insert in the very short length of wire between transmitter and the antenna tuner to check that the transmitter is correctly loaded with 50 ohms (or whatever your transmitter is designed for) then you don't need an SWR meter. You need a TLI. (Transmitter Loading Indicator).

Reg, G4FGQ.

2787. FS: Linx Tech keyfob system RF eval kit

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-03 17:36:10 UTC
From: Brett <b@verizon.net>
Message-ID: <ee%m9.33698$CN2.7776@nwrddc01.gnilink.net>
Source record: 40950
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew,rec.radio.amateur.digital

Linx Technologies Keyfob Evaluation System. EVAL-418-KEY-2. NIB.
This is an evaluation kit that Linx sells for their FCC pre-approved keyfob transmitters and receivers. They are configurable up to 5 channels. This kit is a two-button, two-channel version, operating at 418 Mhz. The kit comes with two modular key fob transmitters, one receiver board, and a spare receiver chip.

The chip set can also be used for passing 9600 baud data, and there is enough hardware here to establish a complete two-way half duplex link. All documentation included.

The evaluation board is equipped with a buzzer and an LED to demonstrate two function capability. However, due to an actual design error in the kit itself, the buzzer doesn't sound unless you reconfigure the modular keyfob.

I'm a bit curious why you care...since any transmission lines you use will likely be quite short compared with a wavelength, and the characteristic impedance of small "50 ohm" coax deviates noticably from 50 ohms by the time you get down ~100kHz anyway. I suspect it would be more interesting to be able to actually measure the impedance, which you should be able to do with one of the classic impedance bridge circuits.

For an SWR meter, if you look at the schematics of HF SWR bridges, you'll find that some of them are simply resistive bridges, perhaps using a capacitor in the detector circuit (which could be scaled to a larger value). If you have a circuit for an HF bridge which uses a capacitive divider, you should be able to scale the capacitor values. If you have one that uses transformers, you can instead use transformers appropriate to your freq range. ~100kHz is much more forgiving of lead length than 30MHz, so it shouldn't be much of a problem.

To make a bridge that covers a 1000:1 frequency range accurately is something of a challenge, but a 10:1 range down around 100kHz should be fairly straightforward.

Cheers,
Tom

Any of the modifications/changes you talk about are not legal. What you have is what you get.

Now you could improve the RECEIVER part. Thats perfectly legal.

Try something simple to start with. Just grab some hookup wire. Wrap it around the existing Receive antenna, or connect it to the receiver you are using. Stick it on the wall and see if that helps. Go from there.

> need special parts,send to me and happy me.

May I suggest you try somebody other than the ARRL for
designs?

ARRL designs tend to assume parts that are available in
the U.S.A. Even us Canadians, right next door, sometimes
have parts procurement problems. If you stick with an
ARRL design you are likely to experience lots more parts
problems than just SBL-1.

Perhaps you should see what you can get, *then* choose
a design. If you can't get high-performance parts, it's
unrealistic to attempt to build high-performance
equipment. And a 20m SSB transceiver is hardly a
beginner's project!

Good for you, the old FM900 has been and gone here quite a few
years back, the latest arrival on the surplus market has been the
Philips FM1000 series, which is a good point in mention, I made up
what I thought was a nice little mod for this radio, I made a little
interface and a program in VB to take control of it using my PC it
has a dynamic range of 140 - 180 mhz,scanning, lockouts, shifts
memory scanning, offsets you name it, and I've had a great deal of
interest in it when I use it, BUT when I say it needs a small home
brew interface then the interest wanes rapidly hi!!

2799. Icom IC-T7H Output power question 2m 4Watts-6Watts

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-03 22:28:45 UTC
From: timfranz@starband.net
Message-ID: <f279398d.0210031428.67442fff@posting.google.com>
Source record: 40962

Hello all,

Let me start by saying I'm new, new to the group, new to amateur radios and I'm a Vol. Firefighter This is why I'm getting into radios. I recently bought a
Icom T2H VHF radio and it transmits great! documentation say 6Watts and I
belive it... I have had many other firefighters ask "What kind of radio is that thing" Now wanting more ability I bought a IC-T7H Transmitting on the same VHF band I get very poor transmit strength (I'm not on low power seting)
I read the documentation and get confused 4 watts with this battery 5W with that one, then again 6W with a corded powersupply... Why would I want a handheld radio if I wanted to be tied to a power source.

Has anyone seen anything on how I can get 6 Watts from this thing? is there a mod? Or can someone suggest something besides using my old radio?
Battery life is not an issue if this is the reason fo the lower output.
I only use the radio for a few minutes to an hour 2 to 3 times a week.

Thanks for any help you can provide.
Feel free to email me at timfranz@starband.net

Tim:

I am not familiar with the particular radios you mentioned, but it is very common for handheld radios to have different power output ratings with different battery packs or external power sources. It is because the different battery packs or external power sources supply the radio with a different voltage. For example, a radio that puts out 4 watts with a 7.5 volt battery might put out 6 watts with a 9 volt battery (or external power source). If you read the instruction manuals where the optional batteries are listed, they will probably indicate what the voltage is.

Second, you will probably not notice the difference between 6 watts and 4 watts under normal conditions. That difference is less than 3 db (decibels) and under most circumstances the station you are talking to won't notice it.

You forgot the last part of that sentence - ham radio is a hobby that serves a public service. And it is that public service that sets ham radio apart from the other hobby or recreational radio users (CB, GMRS, FRS, or whatever).

And please don't now claim that hams don't do public service, because I know for a fact that large numbers do. In fact, based on my experience, the only hams making these claims are the hams not doing public service themselves (perhaps to justify their own inactivity).

> It can not justify the frequencies it has.

Ham operators don't have to "justify" the frequencies allocated to them. We don't allocate frequencies to ourselves - government agencies do. And it is those agencies that have to justify their decisions to allocate frequencies. And judging from the number of bands and frequencies available to us, they have not had a problem justifying their decisions so far.

> 70 cm should be reallocated to commercial use
> since hams do not deserve it.

A bold statement, Barry, especially when absolutely nothing is offered to back it up. Why don't you explain why we don't "deserve" it? Are you going to claim nobody is using those frequencies? If so, I suggest you listen a little more closely. True, the the band is not being used as much as it could, but the same could have been said about the 6m band a few years ago (a band growing more popular each day).

> They may as well have them since hams do not
> need them.

You consistently refer to hams in the third person. Are you even an ham operator? If not, why is this of interest to you? If you are a ham, why do you have such a negative opinion of your fellow ham operators - and such a destructive attitude towards this radio service? Instead of advocating the removal of our frequencies, why don't you do something more constructive - like actually using the frequencies?

From: Dan Tayloe <dtayloe@cox.net>
Message-ID: <3D9D1E84.480DEF71@cox.net>
Source record: 40967

If it is low power, a resistive bridge SWR meter could easily be built. QRPers use these all the time at HF. They would work equally well at LF.

A schematic of such a thing is at:

http://www.extremezone.com/~nk7m/n7veswr.htm

At such low frequencies, the ferrite core and LED should be eliminated in favor of a series combination of a 0.1 to 1 ma meter, a 25K pot and diode. The rf step up transformer was used to improve the sensitivity. You could keep the LED and transformer is you substituted a higher permeability FT37-77 type core.

2807. Air-core coils

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-04 09:10:33 UTC
From: Sidevalve <Sabbatai_zvi@hotmail.com>
Message-ID: <kkmqpu88ppsdv7pirvutoh1ai8h4cghudc@4ax.com>
Source record: 40970

Hi - I just want to mention to everyone that
I am disposing of some airwound (Airdux style) coils.

I won't list them here because I know ads are frowned on
in this group.

If you would like to see some of the coils, I have listed them in:

rec.radio.amateur.boatanchors
rec.radio.swap
AND
alt.ham-radio.marketplace

Thank you & 73

PANEL METERS ALL VINTAGE BLACK MILITARY STYLE UNLESS NOTED

DC AMPERES 0-600 3 SCALES 4 3/4" SQUARE $10.00

DC AMPERES 0-1 SHURITE 2 1/2" SQUARE $10.00

DC AMPERES 0-50 SHURIE 2 1/2" SQUARE $10.00

DC VOLTS 0-5 SHURITE 2 1/2" SQUARE $10.00

DC VOLTS 0-50 SHURITE 2 1/2" SQUARE $10.00

DC VOLTS 0-1 SHURITE 2 1/2" SQUARE $10.00

MAIN LOAD AMPS 0-50 2 SCALES WESTON 3" SQUARE $10.00

DC MICROAMPERES 0-500 2 3/4" ROUND $10.00

AMPS 0-300 3 1/4" ROUND $10.00

HICKOK MODEL 56R 0-2 F.S.=50UA 2 3/4" ROUND $10.00

DC AMPERES SIMPSON 0-50 3" SQUARE $10.00

INPUT AMPS DC 0-200 3 SCALES 3" SQUARE $10.00

DC VOLTS 0 CENTER 50 0-250 2 SCALES DEJUA R330 3 1/2" ROUND $10.00

DC AMPERES 0-600 3 1/2" ROUND $10.00

AC MILLIAMPERES 0-10 SIMPSON 3 1/4" SQUARE $10.00

DC MICROAMPERES 0-50 SIMPSON 2 1/2" SQUARE $10.00

AC AMPERES 0-1.5 SIMPSON 2 1/2" SQUARE $10.00

NOTE ALL IN GOOD SHAPE , All deflect and work fine.
All prices include shipping.

I have pictures of the meters.

Really nice capacitor bank with board and eq resistors already
mounted.
It has the screw type filter capacitors. They are mounted on a
commercial made PC board with eq. resistors. It consist of 15 -
1500mfd @ 450vdc
computer grade capacitors in series. There is room for one more cap,
of
which I have a couple of spares 17 total caps. There are also some
extra resistors mounted on the board you could use to add the last

one.
That would give 93 mf at 7200wvdc. That is nothing to sneeze at! Most of the HARD work is already done for you.
Great for your next high powered project. It will fit in a standard 19" rackmount chassis it is 6" tall 9 3/4" depth
Figure about 25lbs packed weight shipped from 28681 would like 100.00 + shipping open to offers

Source record: 40972

Hi,

For what it is worth, have a look at the following -

http://www.nfbnet.org/weblist/gui-talk/msg10466.html

Stereo needs something like 10 - 15dB more of a signal
than mono to produce the same SINAD, so you might try
switching away from it if that is possible. Another
possibility is moving up toward the top of the band as
shorter whips will be more efficient up there. I also
notice that one of the list posters mentions a tuning slug
round the back which may be adjusted to your advantage.

Cheers - Joe, G3LLV

Don,

Go back to the original Ebay listing to see if the as-is statement is
mentioned... yes, then your out of luck. I've purchased a lot of stuff
from them, all of it just as advertised. Not to mention, as a Canadian
Business, they seem to get items delivered to me faster than any other
North of the US Border business. In fact, I receive their items faster
than many US Ebay sellers work...

In you next post, provide the item number so we can all have a look at the
actual original listing while it's still up.

cheers
skipp

There is no such thing as SWR at these frequencies. Why? SWR is defined as the ratio between the highest Voltage (or current) on the line to the lowest. These are located a quarter wave apart.

You could build a reflected power meter or an impecance bridge, but SWR? If you have a transmission line that is more than a quarter wave long then you can have SWR. A quarter wave at 3 MHz is 25 meters. At 300 kHz, it's 250 meters. At 100 kHz, it's 750 meters. Of course it's really a bit less, depending on the propagation constant of the transmission line.

So if you are operating at 100 kHz, your line has to be half a mile long or so to make the discussion of SWR valid.

I suspect that was what he talked about...it's easy to flip SWR for reflected power.

Message-ID: <ankn6aakv1@venus.btinternet.com>
Source record: 40980

Program TOPHAT2.exe is an improved version of TopHat1.

Part of introductory notes -

"PERFORMANCE OF SHORT, VERTICAL, TOP-CAPACITANCE-LOADED ANTENNAS

Capacitance loading of a short vertical antenna can improve radiating efficiency better than inductance loading. Best possible improvement for a 2/3-height loading coil relative to base loading is typically 3 dB. But a large top hat can improve performance by more than 6 dB. In this program the hat is a number of horizontal radial wires or rods optionally surrounded by a wire circle.

Top-capacitance loading improves radiating efficiency in two ways -

(1) A more uniform distribution of antenna current versus height results in an increase in radiation resistance for no loss in the top-hat. Whereas the high loss resistance of a raised coil can outweigh the benefit of increased radiation resistance.

(2) A tuning coil is always necessary. But its inductance is less when a capacitance hat is fitted and if overall coil dimensions are unchanged then loss in the coil is much smaller. A more uniform current due to a top hat lessens the advantage of fitting the coil part-way up the antenna. The coil can then be combined with the Z-match network located between antenna and the transmitter as in this program."

Download program TOPHAT2 from website below.

I dug out my original Collins 516F2 power supply speaker. Great condition, used with my original kwm-2a which I sold circa 1995 with the PM-1 power supply on the back. When parked, this unit worked great...

So what is one worth now'a days..? I see some ads in various mags by guys buying them direct, but I've no idea what to ask...

your thoughts...?

thanks
skipp

Why is it that we must feel like we need to screw someone out of every penny that we can get for something?? Is that what this hobby and country have gone to?? I have given away parts to various rigs because I didn't have much invested. In fact there were times I gave someone a part to get their rig going just to keep another boatanchor on the air even though I had $$ invested in it. I belive for the most part everyone is not a gold digger. Keep asking an ignore the "freds" that want as much as they can squeeze the turnip for. 73 Larry WA9VRH

2826. Info on Harris RE 6001 mobile repeater?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-05 01:10:33 UTC
From: Randy & Cara Randall <crrandal@earthlink.net>
Message-ID: <3D9E3CE6.8040009@earthlink.net>

Thanks for looking. I am looking for a manual, schematic or any other info on my Harris (RF Communications) RE 6001 mobile repeater. The boards inside the unit were made by Public Systems of Sunnyvale California. From the code dates on the components it looks to be made in 1977-1978 time frame. It is also currently on 153.83 Mhz. I would like to recycle the receiver and transmitter boards for another purpose.

2829. Re: LF SWR

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-05 03:30:32 UTC
From: Dan Tayloe <dtayloe@cox.net>
Message-ID: <3D9E5CD8.4782C1EC@cox.net>
Source record: 40992

I do not see your point is relevant. The man wants to know when he has
a good 50 ohm match to his transmitter. That is the whole point of a
"SWR" bridge. Matching the load to the designated output impedance of
the transmitter is relevant at any frequency. A resistive bridge "SWR"
circuit will do just that, even down to audio frequencies.

What is the point of whether a wave length happens to be very short or
very long? It simply means that some methods of measuring the goodness
of that impedance match work better at some frequencies than at others.

Plans on how to make your own base and mobile antennas, from quarter waves
to beams, quads, and MORE. (These files alone will pay for itself)

UNDERSTANDING coax, swr's, line loss, co-phasing, grounding and MORE. (you
could go to library, copy and forget where you put it..)

CD also includes tuning AND modifications on just about every cb as well as
most 10 meter radios. (for educational purposes) golderscrewdriver is what
$39.95?

Mic wiring to all popular cbs, D104, Sedelata, Turner, standard and of
course MORE. (heck, wanna know whats IN a D-104?)

PLL convertions, adding talk-back, swing kits, roger beeps and MORE
(go to your local shop and ask them to do it, what? more money?)

Packed with pictures, how toos, parts and MORE.

How bout takin a radio and electronics course? FREE
Now includes NTE's cross reference 10.0 program to find over 14,000 parts
!!!! FREE
Schematics, figs, how too's, plus a lot of Amplifier stuff, programs that'll
help you BUILD your own stuff..
need I say MORE?

email for more info, over 130 megs of info in easy to understand format.

Organized for EASY reference.
$20.00

Source record: 40994

Well, gosh, you're absolutely right. We definitely should quit calling them "SWR meters" at _any_ frequency since we can never be sure they are used in lines at least a quarter wave long (unless they are themselves that long). "Reflected power meter" doesn't quite do it either, for those that are not designed to measure power but rather just the ratio of reflected to forward. Of course, those aren't "impedance bridges" either. Even the forward/reflected power thing is misleading, though, unless you calibrate the meter for the line you are actually using it with. Sigh. What's a poor ham to do? I fear we'll be stuck forever with calling them "SWR meters," and understanding that they aren't really, but that they still may give us useful information if we just understand what they really are measuring.

You may also find there is not universal acceptance of the definition of SWR, either, just as a second is no longer defined as 1/(60*60*24) of a mean solar day. The definiton for SWR involving measurement at separate points along the line leaves me with some problems not too different than those with that old definition of "second."

(Now can someone tell me where to find coax which is specified to be within 1% [0.5% would be better] of 50+j0 ohms from, say, 100MHz to 3GHz? Yes, that's a serious question...)

Cheers,
Tom

2833. SMPS problems

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-05 07:33:12 UTC
From: brocktschuler@aol.com
Message-ID: <20021005033312.09238.00000437@mb-da.aol.com>
Source record: 40996

I'm having problems getting a 100kHz switching power supply to work. I want to use this to power a RF amp using a 12V source. I'm using a PWM IC (TL494) and a pair of irf510 mosfets with a transformer core from a computer power supply. The core is rated for 200W and the circuit is a push pull type with a center-taped primary 10Tx2 & 30T sec..

The problem is it takes 8 or more primary turns to get the inductance needed so the primary won't short which then results in a secondary with such a high inductance that it won't put out the needed current, about 1A.

>schematics on one I would be happy with that too.

I assume that you want to know if the antenna is a good load to your transmitter and if not, do some adjustments to the antenna or the loading coil and then measure the match again to see if it helped.

Why not use a noise bridge to directly measure the antenna resistance and reactance ? In this way, you know how capacitive or how inductive the antenna is and thus, you are able to determine how much inductance or capacitance will be needed to bring the reactance down to 0 ohms.

At LF, the band noise is quite strong, so you need a strong noise source. Fortunately, since the typical 135 kHz ham transmitter antenna efficiency is below 0.1 % (-30 dB) this will reduce the noise generator power required.

What's your major? If it's EE then the first thing you do is find out how
the TNC does it's thing. Draw a block diagram and then make this a senior
project. If you need analog design help, email me or send another posting
here. Believe me, you're going to have to do this kind of work sooner or
later if you're coming out here into the real world of engineering. If you
are on the other side of campus, I can't help you. ;-) (Just kidding.)

It's gently trying to tell you that you have selected the wrong core for
this application, at this frequency.

What exactly are you trying to get to, input vs output?

You might salvage the power supply, case, and some of the switches and indicators, but that's about it. Although they sound pretty similar, a modem is fundamentally quite different from a TNC.

However, some programs like MixW allow you to do packet through your sound card, so this completely eliminates the need for a TNC. If the Mac modems indicate you intend to use a Mac for the packet work, though, you could be challenged finding software.

Hi All,

Is it possible to use the tank compnents, coil, plate cap and load cap to make a tuner for 80-10 meters. I have been given 3 Henry Radio Tempo Ones, one recieves (Been stored for 4-5 yrs)(gotta fix the xmit) and the other two for parts. The tank components are intact the all units.

Thanks in advance.

Check out the local ham fleas. Used TNC's can be found for $15 and up, not worth the effort to build your own!

Sure can. Make a Pi net with what you got easy as pi. Or make a "L" tuner with what you got. Check out the radio handbook for details of the schematics. If the Inductance and Capacitance don't match...So what put it together and experiment.

I have one I built from WW2 Surplus parts in a old HB 813 RF deck. Works great.

Dan/W4NTI

According to the following link, the average price on eBay runs around $336.
Definitely worth trying to sell.

==========

Why not ? if the component values are in the right ball park. If the transmitter from which the tank circuit came from covered 80 meters then you should be able to build an antenna tuner to match 50-ohms to somewhere between 50 and a few hundred ohms on the same band. There are a variety of tuner circuits to choose from. Introduce a few switches. Wind a small, extra, self-supporting, 14 or 12 AWG coil if you get stuck.

But it may be the mechanical construction of the components are awkward. For example, if a T-network is envisaged, with two series capacitors, then neither side of both capacitors can be grounded. Insulating pillars will be needed. And what about the 'hot' spindles ?

If you choose a Pi-match then both capacitors have one side grounded. But you may find the max capacitor settings are too small.

You could also try a T-match with one capacitor grounded, the other floating, and the coil connected in series with the 50-ohm transmitter end of the tuner. This is quite a versatile arrangement.

It may be possible to tap into the coil. There is then another 'variable'.

Don't rule out link coupling. It still amazes me how all that power crosses over free space between two coils !

THE VERY FIRST THING TO DO IS GUESS-TIMATE THE RANGE OF IMEDANCES LOOKING INTO THE FEEDLINE WHICH HAVE TO BE MATCHED TO 50 OHMS. One of these modern antenna analysers is useful.

If you are interested in numbers and component values, download from website below programs L-TUNER, TRIODE1, TETRODE1, T-TUNER, PI_L_NET, PI_TANK.

These progs will familiarise you with L and C values needed for the different bands. But you may already be familiar in that direction just by looking at them.

If you want to know the inductance of a coil you already have available, enter its dimensions and number of turns in program SOLNOID2. Do you have a wooden metric school ruler? If you have a lot of coils lying around it's a good idea to label them with inductance values. I have a drawer-full.

As most components are variable it will be sufficient only to get tuner values in the right ballpark. If it will cover 80m then it will be sure to cover higher frequency bands also.

Use alligator clips, flexible hook-up wire, a wooden bench or a sheet of plastic, watch the SWR meter (TLI) and see what happens. You might get it right first time. Think about the size of the box last. I havn't use boxes for tuners for years.

Take your time and have fun !

This is not a practical project.
Most chipsets these days aren't going to support Bell 202 which is the tone
set you need.
Also, you'll have to do 2 wire to 4 wire conversion.
There's more... You'll spend the price of a new TNC in hobby time at $2/hr.

My advice, get a used KPC-3. Nice stable box. The Pico-Packet is also
worthwhile.
Check Ebay, I've picked up nice KPC's for $50.

From: hexter@blazenet.net
Message-ID: <upvl0h1kdl6gc7@corp.supernews.com>
Source record: 40917

Here is the output details,

4000w output pulsed

.6 microsecond pulse width

1250 pps

I found that my feet were exposed to this r.f. source (9375 mhz) of the above mentioned details for about 1 hour, at a distance of about 2 feet from an un-terminated piece of WR-90 waveguide, with a UG-39 flange on the end. One of the other service technicians had removed the X-band dummy load from under my bench while I was on vacation. When I returned, I set up a marine radar unit for testing of the power supply voltage, and component overheating. By total accident, I looked under my bench for a little box of spare parts, and found my dummy load missing, and my radar unit aimed directly at my feet. I have no pain, and my feet were not 'cooking', but I am wondering about my exposure. Should I expect some redness, or pain in a few days? I think the average power output is so low, that I have even less than nothing to fear, but I wonder what limits I have exceeded? (if any)

thanks in advance.

Human feet provide really poor echo returns B.T.W.!

Source record: 40918

A little simple arithmetic shows that the duty cycle of the radar is 7.5E-4, so the average power is only 3 watts. And your feet would absorb only a fraction of this. You'd get more heat from a heating pad, which explains why your feet didn't get hot. This kind of exposure to your foot won't have any more effect than simple heating, which stopped when the exposure ended. You shouldn't see any adverse symptoms.

Relatively low levels of exposure can be harmful to the eyes, which are easily damaged and don't have much in the way of blood vessels to carry off the heat. But to my knowledge no effect other than simple heating has ever been tied to non-ionizing radiation. (Yes, I know there's a lot of investigation regarding exposure of the brain to radiation from cell phones and the like. But as far as I know, there's no direct objective evidence yet of harm. I do agree, though, that caution is in order when dealing with the brain or extremely high field strengths.)

With one or two "partners in crime" I'm working on a DSP system for amateur radio applications using the very cheap 24-bit Alesis DSP, ADC and DAC chipset (about $15 in small quantities). The system will include am Atmel 2313 micro-controller to load the DSP from a host PC, and an EEPROM for standalone operation.

I've designed a prototype single-sided PCB for this system. The final PCB will be double-sided with PTH. Details of this system are here:

Source record: 40921

Way back in 1945, in the RAF, we had a radar maintenance workshop in a bamboo hut in the tropical jungle adjacent to the airstrip. On the bench in the hut was a complete airborne radar equipment including the rotating parabolic dish plus the test gear. Peak pulse power was 50 Kwatt, pulse width 1 micro-second, pulse repetition frequency 1 KHz. Magnetron frequency = 3000 MHz.

It was a favourite trick to stop the dish and stand in the narrow beam which was head-height. Then, when a native of those parts was sweeping the floor or making the tea, I would say the magic words and quickly put a large neon bulb in my mouth which would then light up brilliantly. The native would then drop the brush or teapot and make a bolt for the door.

The only sensation was a the slightest feeling of warmth in the cheeks and a little tickle in the upper and lower eyelashes.

In those days radar maintenance people thought the stuff was quite OK provided it was not directed at the testicles. This rumour was supposed to have been started by Goebels.

Later I visited Hiroshima and, apart from bad dreams, I didn't have any after effects from there either.

Reg.

Source record: 40923

newsguy wrote:
> So far I am liking Debian, just
> looking for others ideas please.

It seems Debian has the best package of aps for hams.
Also they have a website with stable(1), testing(2),
and unstable(3) aps.

Debian would be the best choice except for three problems:

* You need to pay about $40 to get the latest version on
CD-ROM. Those from Linux Mall are a good 6 months out of
date. Also newer aps will not work with older C libraries,
and vice-versa. This means you have to run two versions,
with old C libs and with new C libs.

* Debian is overly, extremely, psychotically wierd about
licensing. You cannot find good aps at the website unless
they are GPL licensed or absolutely free and open. Paying
more money for a CD set that includes the non-free aps is
worth the money. This is certainly true for the non-free
KDE environment. Gnome really sucks. What a hard drive hog!

* Then there is the headache of Debian packages. Debian has
one program, Alien which allows .rpm packages to be installed.
I find that I have to resort to "dpkg" rather than "dselect"
to get some packages to install. You may have to rename
old packages with new package names to fool dselect into
thinking that all dependancies have been met.

As other respondents, I am against Red Hat for three reasons

(1) Red Hat has become much worse than Windows. Too big, only
installs on newer equipment, runs untested and unstable aps,
uses newer interfaces requiring a gaming computer. This means
you have to spend $2000 to run it. Linux was originally designed
to run from the command line. The really useful aps are still
command line based.

(2) Red Hat is worse than Microsoft. MS is guilty of antitrust.
Red Hat knowingly defrauded investors. Don't do business with
criminals.

(3) Red Hat is worse than Microsoft. Their certification is more
expensive, designed to steal from those who do not take the
Red Hat training regimen, and RH only wants to recruit old
time Unix experts. But Linux is not Unix.

The blue blades work because the bluing is selenium gunmetal blue, and selenium is a semiconductor, as is graphite (carbon).

Since blue blades are no longer available at the supermarket, you could just polish and blue your own detector plate, or maybe pull out that 460 Weatherby from the gun locker. Now there is a QRO receiver!

Note: Phosphate finish is not the same as bluing.

Pi would do fine. And keep the insulated shafts. RF likes little human fingers.

Also, the box you use should not be metal. And if it is keep the metal away from the coil in particular. It really don't need shielded at all. Plexiglass does a good job or just use a chasis and make it open to the world. Works fine.

Sort of like what happened to make Godzilla, I suppose. I used to have to work around very slightly radioactive materials on a regular basis and felt the only dangers were an enhanced risk of getting cancer, and of having defective kids. If I'd thought it would make me British I would have quit.

Yes, it is called hard line, but why would you want something so silly in tolerance? It's freq response would be from DC to blue light, but once again, why?

The original question about LF VSWR, it is easy to build an RX bridge at these frequencies, so who cares about VSWR unless you're going to be moving all over the place with a 35 foot whip or something of that sort.

Happy Trails,

> with old C libs and with new C libs.

If you have a fast internet connections, you can download the CD images and burn them yourself. CD sets of the current stable release (3.0), which is about three months old (July release), are also available from a number of sources for less than $40. For example, CheapBytes will sell you an 8 CD set for $17.99.

A problem with C++ libraries is about to hit the Linux world in a big way, now that distributions are switching over to GCC 3.2 (after staying with 2.95 or 2.96 for a long time). The ABI (application binary interface) for C++ changed with in GCC 3. This means that C++ applications built with GCC 2.x won't work with libraries built with GCC 3.x, and vice versa. And you can't just keep the old ones around, because the libraries have the SAME version number, just incompatible binaries.

What it means is that you have to replace ALL C++ binaries (including just about all KDE applications) when you upgrade to a new GCC 3.2-based distribution. This is no problem for apps that come with the distribution, since they will all be rebuilt, but it is a problem for things that you build yourself or download from other sources.

True. But it no longer applies to KDE, which is now free software; both KDE itself and the Qt Free Edition are licensed under the GPL. Debian, however, only offers KDE 2.2 in the stable version, even though 3.0 has been out since May. (The "unstable" version does include KDE 3.)

SuSE is another good distribution for ham use; it includes just about every ham application you could possibly want. You can't download the CD images for free, but you can download the individual packages.

Benny, my first reflex was to tell you "No way, just forget it!" but on reflection.... it just MIGHT be possible. You're basically talking about a complete rewrite of the modem firmware. SOME of the 28.8 sportsters were flash programmable and so, if there's enough flash space and enough onboard RAM, you just MIGHT be able to make it work. Check the US Robotics site to see if your particular model can be upgraded to 56K operation. If so, it's a flash model. If so, figure out what DSP they used, get the programming info and software, learn the DSP language, disassemble the existing firmware (free download from USR) to find out how to talk to the flash, write the new code and loader and you're in business...
If you manage to get this to work, write your Doctoral thesis on it and you're a cinch to pass!

Well, you won't find any off the shelf modems, nor many off the shelf
modem chip sets that support 202. Most of them are designed for phone
lines and even those that claim to support Bell 103 and 212 don't do a
very good job of it. They're too focused on V.90 and 56K for the AOL
crowd. There are a few 202T (four wire, leased-line) modems still on
the market, but they run about US$700 apiece.

But there are some options for 202 style equipment. The
died-in-the-wool DIY fan can work something up with a tone generator
and phase-lock-loop decoder without too much effort. The credit card
industry has been making modems for their terminals like that for
years. Either drive it off your PC or add a dedicated microprocessor
with a few I/O ports, and you're in business. If you plan ahead, you
could even use the same equipment on HF, just provide switching for
multiple shift widths.

I know that there is at least one DSP manufacturer that has a free 202
sample driver in their SDK library. The last I checked, they weren't
going to support full duplex, but that's not a problem for packet use.
I don't know what they would charge students for development kits.

Of course there's always the sound card drivers, and if you can get your hands on some PC/104 cards, they could be made small without much problem. Plus you would have several megabytes of RAM left over for mailboxes, bulletin storage, etc. Or get an old 266MHz P-II for the node. They only run about US$60 now.

Think outside the box. TNC-2 may have been the last one produced commercially, but that doesn't mean it's the only, or even the best design.

One European source is Barend Hendriksen HF Elektronica BV, The
Netherlands if our original poster is in Europe.
<http://www.xs4all.nl/~barendh/Indexeng.htm>. (SBL1 8.85 Euros)
I imagine there are plenty of other sources if the poster is in fact
from Germany, but I am afraid I cannot offer any more help.

The converse is true as well, I have some neat books from the RSGB,
Practical Transmitters for Novices and _Practical Receivers for
Beginners_ which are at the level of building that I'm at (i.e.
newbie), but unfortunately finding equivalents and replacements for
BC107 transistors, ZN414Z / MK484, and the likes makes the projects
far less attractive.

Age enters the equation as well, designs from the 70s or early 80s can
be hard(er) to build, now that some parts have been replaced or simply
discontinued. Since I am very new to building, I don't have the
knowledge to substitute parts.

From: Jim Balls <m0cke@btinternet.com>
Message-ID: <hkgo9.14079$J47.1189440@stones>
Source record: 40850

Hi all,

I'm looking for a design for a 1KW dummy load, I have fround some info on using 13 680 Ohm 5W resistors in oil for a 100W load.
I have found some 50w 680 Ohm resistors which are not wire wound but non inductive only thing is they need a heat sink to run at 50w otherwise they are rated at 5W, would the oil be a good enough heat sink or would I have to look at bolting them all to a heat sink then imersing it in oil?

I would only be loading about 400w into the load

An ideas would be a real help!

Kind Regards,

Jim M0CKE

Simply immersing the bare resistors in the oil will not provide enough metal/oil contact area for heat transfer, so you'll need the heat sink. Since you're relying on free convection of the oil, it will still need to be a pretty big heat sink with the fins vertical in a big can.

The other problem is that you'll have some difficulty in ensuring equal division of current and power between all the resistors - 13 is a large prime number! It would be better to aim for a "cascaded binary tree" configuration, so that at each junction, the current divides equally just 2 ways. (Please don't ask me to draw this in ASCII!)

That would mean either 8 or 16 resistors, but if you're looking at the same UK catalogues as I am, there aren't any 820R TO220 resistors on offer...

So how about paralleling pairs of 680R and 1K resistors to make building blocks of 404R? Then wire eight of these blocks in a binary tree and you're very close to 50R. Obviously the power doesn't divide equally between all the resistors, but with 50W resistors you'd still have a total power rating of 672W.

If you strike out completely check some appliance repair places. I just recently removed a nice motor starting capacitor from the main motor of my 25 year old washer before it was picked up and replaced by a new washing machine.

I would assume appliance repair companies have a way to get them somewhere.

> again, why?

Thanks for the idea, Steve, but unfortunately it must also be
moderately flexible. It will be a component of a calibration system
for instrumentation, and having an accurate, repeatable impedance is a
big help in this particular case. It may be that we'll end up putting
in pads to match the ends to 50 ohms, and trim them for each
individual piece of coax. Yes, we know how to calibrate measurements
at the end of a somewhat arbitrary piece of line, but in this case,
there are difficulties with that. Actually, the 50-ohm requirement
doesn't put a constraint on the loss, and loss of up to 5dB or so at
3GHz in a 2-meter length would be acceptable. I'd expect to fit SMA
connectors on the ends.

We have found line like we need except spec'd to a couple of percent
impedance tolerance, but so far I haven't found anything much better.
Just thought someone here might have a pointer to something better.

Cheers,
Tom

Thank you everyone for your replies, even those which seemed a little jadded. Yeah, I've seen the ebay hype and could easily find some auctions that have closed. But I like the opinions people give out here better.

It doesn't matter to me if I sell it today or never, just thought to ask. The ideal thing would be to buy another KWM-2a, but after seeing a station sell at the Livermore, CA. flea market (last sunday) for $800, I don't think I'll invest in another Collins HF Station.

So back to the closet for now, put it on top of my still in the box unbuilt Heathkit SB-1000 HF amplifier.

chow for now

It might be tough to find anything better. You might look at
Micro-Coax's UTiFlex hand-formable cable assemblies. Semflex in Mesa,
AZ makes everything in house and might be able to design to your
specs. RFCoax is another possibility.

I have been running Slackware for years. But then I haven't really done a distro install in years. I just update the kernel/apps whenever I feel a need to.

You should be able to download the CD images. If you don't have broadband, find a buddy. or make a buddy who does :-).

As far as Kde vs. Gnome, ditch them both. I have used fvwm-95 for years. It is smaller and faster then the two "big boys". I know, it doesn't have the "drag and drop" like stuff, but I have yet to really need that functionality. I just installed Red Hat for another ham (That's what he wanted) and gnome on an older 233 Mhz machine. My even older 150 Mhz machine with less memory and fvwm-95 did the windowing, creating, resizing, moving, etc, much FASTER then his Gnome system. I couldn't believe the difference.

And remember, kde/gnome apps WILL run under different window mangers like fvwm-95, just need the proper libraries, gtk , etc, the app will need installed.

Remember, Red Hat is setup to generate revenue from selling support. You can get Red Hat to be smaller on install. You select the "individual packages" option. Then you can pick and choose exactly what you want instead. On my buddy's system my first install doing it without that option resulted in over 1.5 gigabyte. Never had one anywhere near that on Slackware. Redoing it with the above option and picking and choosing brought it in around 900 Meg, about half. figured it I left out gnome window manager and used fvwm-95, it would have been about 300 megs less. But, he wanted Gnome.

Plus, RH does not install tenetd, sshd, ftpd by default. They consider that a security risk. Inorder to install them when you start, you HAVE to use the individual packge option.

I have a couple of linux ham apps, a Kenwood radio control program and an APRS app on my web site below. Plus I am about ready to release echoLinux, an ilink/echolink for linux, native to linux this week. I have been alpha testing with a few others and it works fine.

Thanks to everyone for your suggestions and information.

I have been playing around for the past week or so with different oscillator types. The one suggested by Leon so far seems the best in that the output signal level is pretty constant over the tuning range of the variable capacitor, although the signal integrity at the source is "pants". I have now followed it with a 2 transistor (bootstrapped?) high impedance amplifier taking the signal from the main tuning coil (as suggested) via a very small capacitor (currently the inter row capacitance of the breadboard ;-). Having performed a fourier analysis in my head, signal integrity looks pretty good.

Bizzarely I am seeing some strange effects at a certain frequency, where the oscillator appears to be modulated by a regular "digital" signal. I live very(!) close to some mobile phone masts and I am wondering if I am picking up what is presumably a very strong signal??? No wonder none of my RF projects ever work!

The superhet is a very basic design, dual mosfet mixer, soon to be 3 transistor local oscillator, uses Denco tuning coils circa 1980, 2 transistor IF stage, TBA800 audio amplifier. I built it when I was 15. It seemed to work quite well (given that I had no test equipment to align it) with the single transistor LO/mixer, but performance dived when I made the improved circuit with the dual gate MOSFET.

Finally I am still trying to find out what signal level I need to inject into the MOSFET, Volts or milliVolts?

Ha, I'll bet you could get a grand or better for that unbuilt SB-1000 amplifier. I think that you already know that. Why put the 516f-2 back into the closet when you are not going to invest in another Collins? Nothing jaded about my reply, seems as if you are a very good at fishing though. Chow for now. 73 de Fred.... Oh, PS, I have a very nice looking/working Hallicrafter SX-115. I wonder how much its worth? Any ideas??? Lets see, also an excellent KWM-2/with good 516f-2/664 electrovoice mic/w clamshell base. Hummmm, I wonder. So, how much for your 516F-2???????????

We've been using terminals from Datatrol since the early '80s when we
quit using Burroughs equipment. Their 202 based terminals have always
used tone generators and PLL decoders. They were far more reliable and
durable than anything we ever tested with the modem chips. The last
leased line model was discontinued two years ago, but we still have a
couple thousand of them in use, some more than 12 years old.

What do you mean "oil?"

Motor oil? NO -- it'll burn.

Mineral oil? NO -- not enough heat transfer capability.

Transformer oil? YES -- but be certain it's PCB-free; if it's made in the
past 20 years it should be.

Why not just purchase an MFJ 1KW dummy load -- I think they still sell one.

Jim, while I don't run that sort of power into my dummy load. I have
used 10 560r 1/4 watt resistors in a 8 ounce bean tin full of
sunflower oil as a heatsink. I've run 100w into it for a short time
without problems.

Actually mineral oil is often used as a second best substitute to transformer oil. I've used it in my Heath Cantenna for over 20 years with good service results. Even took it to work once and terminated a 3KW transmitter while we tuned on it for short periods when we needed a dummy load and none was available. Sure, it did boil after a while, and of course we were careful to transmit into it only for short terms, but it worked out OK.
But by all means if you can find transformer oil that you can get, do it.

And, subsequent to the big scare over PCB's, it was found that only after they're burned or charred do they become so toxic and dangerous. I don't think that changed their legal status, though.

Dick

Ok everyone, here's another question. I have a PS out of an old 386 computer. Is there a way that I can use this as a PS for my ham radio. I have searched the internet and have found a few articles but nothing that really helps. I have read different things about including a resistor in line with something. Basically, is this possible, I imagine that it is. One problem i see is that most radios run off of 13.8V while a PS puts out +12 & -12

Let me know what you think

There was an article in QST about 6 months ago on this very topic. I
believe it was mentioned on this group, as well.

As I recall, you want to put a stable load on the +5 output of the
computer PS, because the +12V is unregulated. You then tweak an
internal adjustment to bring the +12 up closer to +13.8. You don't
have to hit it exactly but higher than 12 is good.

There are amperage limits on the +12 circuit. Should be fine for an HT
or a lower power xmit mobile.

Probably work out fine, transmission fluid is designed to conduct heat away from the transmission to be dissipated within the vehicle's radiator, and it should handle the job well.

There has been a lot written about this over the past few years, including the QST article Gary mentions. Search for "St. Louis" switcher (don't know why it got that moniker). Maybe check the IAQRP and NJQRP sites. I think it was popularized by either the Iowa club or perhaps the Flying Pigs. I'm sure NJQRP had something in one of their mags, and they tend to have a lot on their web site. There was also something in ARCI's QQ, but they tend to not publish journal articles on their site.

It's fairly easy to hose a modem chip design.
Not decoupling the supplies properly will do it easily, or having the
crystal a bit off freq.

2928. Re: PC power supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-09 07:58:57 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <ao0nk2$ibkh6$1@ID-61331.news.dfncis.de>
Source record: 40891

I'm using a PC power supply from an old Compaq to power my rig
http://www.hanssummers.com/radio/polyphase/index.htm and find it excellent.

The rig uses +12V for most of the circuits and +5V for the frequency counter
and clock. One worry was switching noise from the PSU since they are switch
mode - to combat this possible problem I used a large toroid and a 10,000uF
capacitor on the +12V line, and I haven't noticed any noise problem. When I
tried a linear power supply
(http://www.hanssummers.com/electronics/equipment/psu/index.htm) the noise
was actually worse and then there was a 50Hz hum as well.

One thing to look out for: I have bought 4 new standard PC power supplies
for my giant LED display project
http://www.hanssummers.com/electronics/equipment/riskometer/index.htm for my
employer, and they do not seem to feature short circuit protection. If you
accidentally short them you get a spark and a loud pop. Opening the box
reveals the fuse completely fried. Replacing the fuse and powering up
results in a louder pop, a larger spark, no blowing of the fuse, and a large
green 2-leaded ceramic component somewhat resembling a fat ceramic capacitor
physically explodes. I am not impressed with the design at all, why they
include a fuse if it's that useless is a mystery. They've obviously cut the
component count to a bare minimum. So far I've blown 2 power supplies this
way.

The point of the story is that I have shorted my rig's PC power supply so
many times I can't count. It has automatic protection which cuts the power.
To reset it you press a reset button on wires from the case - breaking the
connection. It's great (well done Compaq). If you can get a decent power
supply like this you will be a happy homebrewer.

If you can find out what Gore uses you can try that or use semi-rigid coax. I also find 400 and 600 series coaxes to be fairly flexible and extremely well characterized. Try Times Microwave or CommScope for details. They also have flexible cables characterized to 60 GHz or more. You need more flex? Go to flex circuit and build your transmission line using coplanar waveguide. See Agilent's web site for AppCad 3.0 which can help you design the flex. I would stick with the non groundplane waveguide because it would maintain the TEM mode of transmission and wouldn't require the grounding considerations of the grounded guide.

Please forgive the slightly off topic subject but I think this is probably the one ng that will have subscribers that:

a. Know what I'm talking about
&
b. Might be able to help.

The other day I decided to have a nostalgia trip and do some design work the old way using my long retired Pickett slide rule, this was a mistake as it became quickly apparent that I'd totally forgotten how to use the specialist scales !!!! Now I know it's possible to use the rule to do the electronic design calculations I wanted but could I b*****y work out how those scales operated.

Has anyone out there ever owned a Pickett N-16-ES Electronic(s) Slide Rule and, more importantly, can remember how to use it ? Even better, does anyone have a copy of the instruction booklet hidden away they could scan in for me.

I think my instruction book went adrift 30+ years ago, you know - about the time when you're so confident in using something that you tell yourself it's like riding a bike, something that you'll never forget ..... I know, been there, seen it, got the T-shirt !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

There is a Pickett web site but this particular model doesn't seem to figure on it for some reason.

Dick

My initial reaction was yes, I know what an N16-ES is, and I have one right here in the desk. Well, I remembered badly. I have an N3-ES, an N4-T, and an N300-ES, but no N16-ES.

Still, I felt sure I could remember how to use the log log scales once I looked at them. Wrong again, after decades, that part of the gray matter seems unreachable. The site Peter points to has a nice Pickett tutorial, but it stops short of the log-log scales.

If your question is about the CI or L scales, the tutorial helps. But if it's the LL1 thru LL4 scales, it doesn't. The others seem mostly obvious (although the CF/m seems a little baffling, too). Still, if you find a source, it would be great if you post your findings here so us other old guys can benefit!

2934. Direct conversion radio receiver module for DSP baseband processing

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-09 17:40:57 UTC
From: Leon Heller <leon@heller123.freeserve.co.uk>
Message-ID: <ao1pqu$t77$1@newsg1.svr.pol.co.uk>
Source record: 40797
Cross-posted to: comp.dsp,rec.radio.amateur.homebrew

I've designed a little direct conversion radio receiver module (2" square)
ideal for use with DSP systems. It's easy to build on a home-made PCB.

It's intended as a component in a high-performance receiver, and was
designed for maximum flexibility, in that it only includes the mixer (an MCL
TUF-1), audio diplexer and low-noise AF pre-amplifier. Input filtering,
oscillator, AF filter etc. are all external.

It may be used in many receiver configurations: as a simple DC receiver,
binaural receiver, phasing receiver, etc. It's ideal for use with a DSP
system.

Full details, including several pictures, are here:

http://www.geocities.com/leon_heller/dc_rx.html

73, Leon
--
Leon Heller, G1HSM
leon_heller@hotmail.com
http://www.geocities.com/leon_heller
(only three links) and
it's exactly 2" square, a nice round number. 8-) Like all my stuff, the PCB
is easy to make at home: all the tracks are on the bottom and there is a top
ground plane.

It's intended as a component in a high-performance receiver, and was

Wow - Log Log scales. On the Keuffel & Esser Deci-Lon and Post Versalog 1461 rules next to me.

They're used for finding arbitrary powers, roots, and exponentiation. So, if you wanted to out how much brighter an incandescent lamp appears at 130VAC instead of its rated 120VAC, and you knew that apparent brightness is proportional to the voltage to the pi power (an approximation), you would use the C and D scales to find 130/120 (or 1.083), find that on the LL1 (or Ln1) scale, put the C scale's index (1) above it, then look below the C scale's Pi value. Since you'll use the right C index, you've wrapped around from the LL1 to the LL2 scale and get about 1.286 - i.e. a 28.6% increase in brightness.

Fun old things, aren't they?

These power supplies require a minimum level of current drain, a few ma, to stay "regulated".

I have used the torroids from a number of blown supplies for switching supply projects.

Yes, that's true. Every PC power supply I have used will cut out unless a certain minimum current drain is taken. According to the PSU datasheets the minimum current drain is sometimes as much as 4A. However in practice I have found this amount isn't needed to achieve good regulation and prevent cut-out. On my home PC I use a car headlamp bulb on the +5V supply and it works fine. Other times I have used a high wattage 10-ohm resistor and it works just as well.

Peter it would help if we were told things like..
its function, manufacturer, encapsulation etc..

at first sight it would appear to be a Hitachi device, possibly a
'special' embedded controller. but this is only guess work.

Considering the cost of these supplies, the startup problem shouldn't be
hard to live with, I would guess. If you had the equivalent linear
supply, it would weigh a lot, take up a lot of volume, and cost a
fortune. Of course, it would be self-starting (if properly designed) and
it's line output would be fairly clean with very little radiated energy
from the circuit board. It could also be that some supplies may not need
a minimum load depending on the vendor, etc, but are you going to want to
buy different ones and test them? My recommendation is to do what you
have to do for your application and live with some pain. Perhaps, and I'm
not certain of this, a temporary load at start up may get the supply to
work for your application. Once the regulation gets going, then you can
take the load off and still have the required voltages. All I can say is,
try it and find out. Use a timer circuit, relay or switching transistor,
low value, high power resistor like Hans recommends and see if it works.

The IC contains:

(logo Hitachi) 8E1

HD 63701 VOP

we found a chip from the same family the HD63701 XOP it seems to be an 1.5
MC controller from Hitachi

http://www.google.nl/search?q=cache:gEUaQBhnLrMC:www.equinox-tech.com/chipdi
r/f/mcu.htm+%2263701%22+micro&hl=nl&ie=UTF-8

on the Hitachi website I could not find anything, properbly too old

with google we find a lot of equipment which was containing this family of
controllers and place to buy them in large qty, but so far no real
data/sheet application sheet or so etc. , so any help is appreciated

Best regards,

Peter, PE1CUO

2948. Re: Pickett Electronic(s) Slide Rule Model N-16-ES

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-10 09:27:22 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uqahvt6os6tdf1@corp.supernews.com>
Source record: 40812

I a. Know what you're talking about - I have an N-16-ES too. But b. Can't help. Found the manual for my trusty N-4-ES, although I think I could still do just fine without it. But I never used the N-16-ES much, and didn't come across the manual. You might have trouble finding anyone willing to scan the N-16 manual if it's as thick as the N-4 manual. Good luck!

If you're pretty sure that it's Hitachi, I would send an email to one of
their applications engineers and ask them. If they don't want to look,
then ask them to kindly hand the request off to one of their collegues who
is an amateur operator. They would probably help you.

BTW, these big companies are just that, big, so be sure to ask the right
division of the business. If the part is digital LSI, then go for that
division and so forth. For instance, I was very knowledgeable about
linear ic's, but if you asked me about DSP's I would very foolish.

Please forgive me for barging in to this with the ad below, but it does
follow suit!

In the last month or two, I've noticed a surge in interest locally and on
here, for using PC supplies for equipment.
Any one in need of some PC supplies? I have some that were removed from
"working but scrapped" systems from a 286 - up...CHEAP! Also have the line
cords to go with them. Lots of other stuff too!

Actually, the cables we use now are from Gore; they're pretty good
(and maybe better than Gore guarantees by enough...need to make some
measurements on that). Gore makes their own cable, AFAIK (and I have
that on pretty good authority...thanks, Barry!) I have the feeling
that Astrolab may be pretty good, too. I also have a recommendation
for EZ Form (EZ Flex)...we'll check that out too. (From the EZ Form
web site: "The cables exhibit highly favorable
electrical characteristics, particularly an impedance tolerance as low
as +/- 1/2ohm for a .141" diameter cable with nominal impedance of
50ohms." So there's hope, but that's a semirigid line, I believe.)

I think we have some better SW around here now for flex circuit
design, but fear that manufacturers would not be able to hold the
tolerance needed. It's a thought worth checking out, anyway.

Thanks, Steve, and all the others who have posted and written!

Cheers,
Tom

2957. Don't Build This at Home or Anywhere Else.

Newsgroup: rec.radio.amateur.homebrew

From: martin@okstate.edu
Message-ID: <ao4lgp$62g$1@hydrogen.cis.okstate.edu>
Source record: 40820

I recently made a very interesting mistake in designing a digital logic circuit so I thought I would describe what I did and maybe save a few of the rest of you some trouble.

I have been experimenting with digital logic for several years and thought I had made most of the really bone-head errors in design, but this particular bad design totally sneaked up on me.

I wanted to make a variable clock generator to drive a switched capacitance filter. I did not have a digital comparator chip on hand, but I do have some CD4040 12-stage counters and some CD4048's which can be configured as 8-input and gates. These are slow, ancient chips, but they were okay for the speeds involved, here and the problem I created is more of a mental software problem than hardware related.

And gates set their output high as soon as all their inputs are high so I thought it would be possible to make a divide by N counter by simply connecting various combinations of counter outputs to the inputs of the and gate. The idea was that unused inputs would stay high. When the counter reached the desired count, the and gate would see 8 high inputs and the counter reset could be activated by the output of the and gate.

This actually does appear to work but there is a hidden major flaw that I didn't even think about until I had wire-wrapped the circuit and was testing it.

If you do this, you will always loose the least significant bit.
If the first bit was the LSB, it is as if it was always set.

A very short truth table says it all.

Let's say the first and second bits are connected which is a divide by 3 counter.

It will work as you would expect.

Starting with all 0's on the counter, A goes high, then A goes low and B goes high. Finally A and B go high and the and gate sees true.

If the A output of the counter is disconnected and left high, then the and gate sees true again as soon as the counter reached 3. This is so obvious when looking at it now, but I completely missed it when wiring up the whole circuit.

If one wants to build a comparator, the only way to do it is to use exclusive or gates for each bit and then one can Or all those outputs.

In my circuit, I have DIP switches connecting the 8 counter bits to the And gate inputs with pull-up resistors on all And gate inputs. Opening a switch leaves that particular input in a high state.

I knew I was in trouble when I flipped the 1's position switch and the frequency of the output did not change.

As soon as I double-checked that the circuit was as I meant it to be, it hit me why it wasn't working.

I think I should look for some programmable counters and do it right.:-)

Hey Joe:

Wow! How about them prices for slide rules nowadays!

Back a few decades [That was in nineteen umpty-umphhh.] when I bought my first slide rule, it was a Sun-Hemmi, ivory coated, engine engraved, bamboo log-log rule, it cost me almost a week's pay, $35.00. In those days I was earning $47.00 per week.

Today, in mint condition, that baby sells for about $350.00.

A few decades later [That was in nineteen umpty-umphhh plus plus.] I bought a new HP 35, reverse polish, electronic calculator for $350.00 and finally retired my trusty log-log Hemmi rule.

I can buy a good color TV now for that same price.

I kept that log-log rule in a box in the attic for decades. On rainy Sunday's I would often get that rule out and reminisce with it about all of the beautiful electronic/electrical systems that rule and I had designed and put into production together. I always considered it to be my lifelong professional friend!

Then... a few years ago, when we were moving between States, my dear wife Mary held a garage sale while I was out of town, and she sold that precious log-log rule for $0.50! I wondered at the time if that was grounds for divorce?

Such a despicable act is almost on a par with coming home and finding that your wife has had your favorite hunting dog put down cuz he peed on the carpet!

Best,

I live in NE TN -- right on the VA - TN border -- the state line is 100 yards from my back door.

At Exit 45 on I-81 as it goes through SW VA is the town of Marion, VA.

Marion is the home of author Sherwood Anderson who edited the local newspaper and is buried in the local cemetery. It's also the home of Hungry Mother State Park, a very nice Virginia state park.

As with so many large towns/small cities, its downtown fell victim to WalMart (spit). A couple bought the old post office and have turned it into an antique center. He teaches math and physics at several local community colleges -- and he collects slide rules.

So -- if you are ever through southwest Virginia on Interstate 81, watch for the Marion exits -- three of them -- between exits 40 and 50 -- go into Marion and find the old PO antique shop on Main Street -- you can't miss it -- and browse his collection -- he even sells them

Of course, you could have used pull-down resistors instead and it probably
would have worked. The inputs don't have to be pulled up, they just
shouldn't be left floating.

There is a story written by Isaac Asimov back in the 40s or 50s, oddly
predictive, called "A Feeling of Power".

It looks at a future where all calculations were done by computers and
calculators, but one man rediscovers how to do them, using pencil and
paper.

Happy trails,

I've got a power supply that outputs about 300v. It specifies a 47uF 400v cap on the output. What I have is two 22uF caps rated for 200v. If I parallel them I get 44uF, close enough. But does the voltage rating add as well? How does cap voltage rating work?

In parallel the voltage rating will be that of the lowest unit. In
your case it remains at 200. If you put them in series with a pair
of balancing resistors of perhaps 10k, you will be usable to 400v, but
will have only 11mfd of effective capacity.

No, the voltage rating doesn't add. The voltage rating is that of the
lowest capacitor. (in your case both are the same so it stays at 200 volts)

You can put the caps in *series* instead. Add an equalizing resistor across
each capacitor - maybe 10K ohms or so. (be sure to do your math on the
power ratings! - there'll be what, 15mA of current flowing)

The problem with that is that capacitors in series may add in voltage
rating, but they *divide* in capacity. Two 22uF caps in series exhibit 11uF
of capacity. Your circuit may hum, depending on other constants.

I'm afraid you're probably going to have to buy a bigger capacitor.

I don't think you will find one. Your best bet is to make your own. Buy a couple of suitable transformers for the 5V and the +/- 15V supplies, some rectifiers and capacitors and add your own regulators. You can get 5V regulators that will give 2A or more, and +ve and -ve 0.5A regulators for the +/- 15V. The circuit is quite trivial, making a nice case for it is probably the hard part.

Micas of that value and voltage rating seem to be pretty scarce. However, RF Parts does have 10KV .001 "Plate coupling capacitors" for 2.45 and bypass caps of the same rating for 1.65.

Unfortunately they have a pretty hefty minimum order, $25 I think, and most of the stuff they have is pretty high priced, so it can be hard to find that much that's worth buying (at least for me). But, if you need a couple of 3-500Z's that'll make quick work of that minimum ...

Anybody got a source for small silver-mica caps in production quantities?
I'm looking for stuff in the 200V/820 pF sort of range, current production.

Rapid Electronics (in the UK) stocks production quantities. They are all
500V. Price for 820 pF is 1.23 UK pounds each, one off.

>shouldn't be left floating.

They shouldn't be left floating all right, but using a pull-down
array would create a new problem.

With an And gate, all inputs must be high for the output to change state
from 0 to 1. Think of 8 series-connected Christmas lights or single-pole
switches. All 8 have to be closed to make a circuit. With an input tied
low, the output would never get to go high because there would always be at
least one input low. You did make me catch my breath for a second,
however.

What I will do after I finish clearing all the previous circuit
away is to stuff a pair of exclusive-or chips on to my board. The ones I
have contain 4 XOR gates so two will give me 8. The XOR truth table is
satisfied when inputs A and B for each gate are unequal. The output is
always 0 or off if A and B are equal. One input of each gate will go to
one input on the counter. The other input of each gate will go to the DIP
switches which will be connected again to pull-ups so that every closed
switch is a 0 and any open switch is a 1. When the counter equals the DIP
switch setting, all 8 XOR gates will show 0 at once.

My 8 input And gate now needs to become an Or gate and everything
should work this time.

Since others have answered your question I'll just mention something a
little odd that I've found with electrolytic capacitors. The axial
configuration seems to run about twice the price of the radial
configuration for the same-rated device. Being a cheap-o myself, I
therefore use radial filter caps in all my tube power supplies. I
like Mouser (http://www.mouser.com) as a supplier.

I don't know what you mean by production quantities. RF Parts prices in
100's, I suspect if you need 10,000's they would be drained pretty quick.

Interestingly, for 820 pF, their price on 300V is about twice the price of
500V. (of course, there's always that size thing!)

I don't know of any other reliable sources. Usually I try to stock up at
hamfests. Dan's usually has DSM's at good prices, but he has what he has at
the time, and certainly not 'production' quantities, although his prices
will be way better for what he has.

Cross-posted to: alt.ham-radio.mods,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,sci.electronics.design,sci.electronics.equipment,sci.electronics.misc

I recently read a post where a gentlemen is using a Wavetek Sam I catv analyzer as a 4-400 Mhz spectrum analyzer at low cost. Is this possible and how does such a unit compare with regular commercial spectrum analyzers? I'd like to find out a little more about this unit... is it solid state, can it be used at 50 ohm impedance, accuracy specs, step attenuator, easily serviced, etc.... so I'd appreciate any such posts from someone using this unit as an RF analyzer.

Thanks,
AJ

Basic electronics 101:
Series capacitors divide the capacitence, and multiply the voltage.
Paralell capacitors multilpy capacitence and voltage remains the same as any
one of the caps in the circuit. Simple as that.

Last time I visited James Van Allen (yes, still teaches the MS and PhD
physics seminar classes at 90 !)
in hias office - he was dispossing of some of his slide rule collection (big
55 gallon barrel).

I thought abou an eBay sale - but no onw would ever pay more for them (even
with an letter of authority signed by him)

I guess if you read that a certain way, it's sort of correct. But it's misleading.

Basic electronics:

Series capacitors: C = 1/(1/C1 + 1/C2) and add the voltages. You'll also need to add an equalizing resistor in parallel with each C (as another poster already noted). If the voltage ratings of the caps aren't the same, you'll need to adjust the resistance values accordingly (better not to use caps that aren't the same).

Parallel capacitors: add the capacitances, and voltage = the voltage of the lowest rated cap (as another poster already noted).

... Rich

Digikey carries Dipped Silver MICA caps made by Cornell Dubilier GC/Waldom, the 500v/820pFs are listed for $1.33 in 100 qty. Page 660 in their latest catalogue. I believe if you call them you can get pricing for 1000 and 10,000 quantity.

This actually brings up an interesting point though. This is a pretty hefty price for a cap. What would be the closest equivalent to the S-M that doesn't run quite so high?

Actually, that should be a NOR gate, if you wish to have the output high
when all the inputs are low (A=B). I reread your original post and saw that
you started this exercise because you didn't have any digital comparators,
so there's no sense bringing that up. Nor programmable counters either,
apparently. There are plenty of ways to skin this particular cat. It's
nice to see somebody experimenting and learning while getting hands-on
experience with hardware.

It's not going to be nearly as good as a spec analyzer. You can see spurs
and harmonic and non-harmonic distortion with a real SA,and better
accuracies. The SAM is basically a freq-tuned voltmeter.Made for 75 ohm
impedances,that's what cable is. You could use a 50-75 ohm pad,but accuracy
will suffer.
(I used to work for the company that Wavetek bought,that made the SAM
meters. Mid-State Electronics, ;-))

I'd buy one of those inexpensive SA's before I'd spend any money on a
SAM,if you want a RF analyzer.

I didn't realize DigiKey carried DSM's, they are my favorite supplier.
Those prices are similar to RF Parts price for 300V units, almost twice
their price for 500V. Interesting since it's pretty rare that anyone is
more pricey than RF Parts.

One caveat about DigiKey ... be sure to specify what you want for shipping.
Their default is 2nd day air, which is pretty expensive. Where I am at
least, 2nd day air takes 2 days, costs about $25. UPS Ground takes 2 days,
once in a rare while 3, costs $4.50. Rarely is it worth $20 to me to be
guaranteed 2 days instead of almost always getting it in 2 days!

No you should not use it as spectrum analyzer unless you only need a very simple, low resolution and poor accuracy analyzer.
Bye.

2991. Homegrown Li-Ion battery pack for FT-50

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-12 16:26:37 UTC
From: Markus Baertschi <markus@markus.org>
Message-ID: <MPG.18126b92f95c6e1b98968d@News.CIS.DFN.DE>
Source record: 40704

I recently got an almost new, but mechanically broken Lithium-Ion laptop battery-pack. It contains 6 3.6V 1.8AH battery cells. Two of those could make a perfect 7.2V 1.8AH battery pack for my FT-50r. To charge the pack I'll use a MAHA 777-plus universal charger.

Am I overlooking something ?

If no then I'll just have to find a broken battery pack te re-use the housing.

Markus

It is a formula to calculate the self capacitance, wonder if somebody
can use it? Measurements of my frame antenna is

119kHz C=800pF Q=175
136kHz C=550pF Q=150
140kHz C=500pF Q=150
150kHz C=380pF Q=150
200kHz C=145pF Q=115
240kHz C= 50pF Q= 75

See article in Electronics World (Wireless World) nr 8/2002 about
frame antennas for receiption on 136kHz. I've made some sketches for
my version, they are available as small gif files if you send me an
email

My calculation shows the self-capacitance = 708.8 pF.

My technique is to plot 1/F*F (1 over F squared) on the X axis,
resonating capacitance on the Y axis. Then do a linear regression fit
and you will get the y intercept when x=0 as a negative number. This
number is the self-capacitance.

The advantage of this technique is that it makes use of all of your
measurements, not just one or two measurements.

I've plotted your data and will e-mail the plot as a PDF file.

Never owned one of those... but this is wonderful.
I have a home computer, but I never really think of it for doing mathmatics. I usually grab a pencil and paper. Then I went cleaning the place and found my two old Pickett slide rules. One was a simple trig and the other a log-log. This made math fun again. And they were fast. At least as fast as trying to call up the calculator in windows.
For the simpler things, it is rather like riding a bicycle... you don't forget. For me anyway. But then, when I was going to school there was no such thing as a pocket calculator and the slide rule was actually a college course.
Just coolness.

Well,there's the TEK 1401 or 1401A,that was designed to connect to the 323
scope and had BW up to 500Mhz(can be used with other scopes,too).

Or there's a 7K mainframe(7603) and a 7L12 or 7L13 SA plug-in,which goes
10Khz-1.8Ghz.Or find a 2710,2712 portable SA,looks like a 2213 scope,goes

to IIRC,1 Khz-1.8Ghz.There's several HP analyzers available used,too,but I don't know model numbers for HP. You need to peruse a few used Test Equipment company catalogs. Google ought to turn up several.

There's also an inexpensive SA I've seen listing for about $1500 new,I believe it comes from Taiwan,and marketed under several companies name 'brands'.I saw them in hobby electronics mags like Nuts&Volts.

SA's are not cheap.

2998. Repairing my Yaesu FT-847

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-13 01:08:40 UTC
From: Larry Bratcher <lbratche@swbell.net>
Message-ID: <sl3q9.5857$K_.990836806@newssvr30.news.prodigy.com>
Source record: 40711

I think I have screwed up big time! I was moving stuff around in the shack, had everything pulled out an was re-arranging things. In this process, I accidentally hooked my FT-847 up with reverse polarity! It popped and smoked and of course it is now dead! I took the cover off and looked for burns, but did not see anything obvious. The fuse is good but it does smell burnt inside. I'm not a repair person so I am in need of a reference for a good Yaesu repair person or would I be better off sending it back to Yaesu? Any thoughts on what I may have damaged.

Thanks

Larry

Hi Larry,

If you were lucky enogh, only a diode inside the PA might have burned.
Usually there's a high current diode inside the PA, its purpose being
exactly that of protecting the PA and maybe the rest of the tcvr against
accidental reverse polarity supply. Hope that's all.

Good luck,
Cirip

Why not measure your SRF and calculate the Cp? You could then verify it
against the other data if nothing else.

At these frequencies that should be a breeze.

In the September and October 1989 issues of Radio-Electronics, there is an article by Fred Baumgartner on a build-it-yourself spectrum analyzer. The "hard part" is done by a Zenith TV tuner module that converts 50-600 Mhz to 63 MHz (Channel 3) output. This is followed by a TDA7000 FM receiver chip. There is a 555 to generate the swept tuning voltage for the tuner and another oscillator for sync. They were selling a complete kit of parts for $187 in 1989, which is around $280 today.

Hi All

I'm trying to build a synchronous AM detector for use in a DX TV receiver.I need to use a discrete version rather than use one of the TDA-series IF and detector ICs intended for consumer TVs. If anybody can steer me towards some schematics I could as a starting point, I'd be grateful.

TIA

======
With the fuse reportedly still 'good' it seems there is NO reversed polarity protection diode inside the transceiver.

My advice would be to have an external hefty 40 Amperes diode (connected reverse polarity) across the transceiver's power input with a separate (rig rated) fuse on the supply side. Upon reverse polarity connection the diode will conduct and blow the fuse.

Alternatively , reverse polarity connection can be avoided by using Anderson PowerPole connectors ,available (I believe) for a current rating to up to 30 Amperes.
See also QST - Oct 2002 ,page 59.

Note : For low(er) power consuming devices , like a TNC I usually fit a diode in the supply line ,accepting the 0.7 voltage drop across the diode. This is also done in leads to portable measuring instruments requiring external DC power.

With 'the protection module ' ,do you mean just an internal fuse ,or
something more elaborate ?

Try the National Semiconductor web site for app notes on balanced mixers, etc. They will all be in the linear ic app's.

If you maintain the original package for the battery and use the same charger, you won't get good charging curves, but the protection circuit should still keep you from blowing up. Otherwise, use a constant current charger with a low charge rate. It'll take forever to charge fully, but it is better than nothing. For this type of app, I usually set my power supply for a voltage above the final one of the battery and set my current limit at C/20 where C is the capacity of the battery (e.g. 1200 mAH C=1200 mA). I usually also making up some charger contacts using paper clips and alligator jumpers to my supply.

Purists, please don't flame me. This is far from optimum, but this is not a quest for perfection. The poor guy needs something cheap not fantastic.

First thing to check is the power supply voltages.

Should be a CD ROM version of the manual on eBay. Don't
know how good it is.

Pete gives great advise. That is always the one thing that I check first. Also try the timebase if you have a scope. If you don't, then use a DC meter on the clock out and see if the voltage is midrail. A 5 vdc clock running at 50% duty cycle should give you an average of 2.5 v. Both methods involve testing with no documentation. If you still measure okay, don't stop there. These are preliminary readings.

I almost forgot! Look for "fog in the cockpit". Sometimes, you'll do something silly like put the thing in external time base (switch on the back of the unit) or hit the wrong resolution switch. I, for one, won't laugh at you if you come back on the forum and say something to this affect. I've done it a zillion times and I've been doing this stuff since 1962. I guess I'm human and my engineering degree doesn't qualify me otherwise. :-)

Happy Trails,

If it is not anything obvious in the power supplies, a fairly common fault used to be the power transformer pins making poor connection to the mother board, or even breaking off. Make sure the transformer is firmly fixed in place. There are tell tale LEDs on the power supply boards btw.

Due to the size of the foldouts, they are hard for me to scan, but ask if there is anything that I can help with.

With the book, easy, without it, a nightmare!
Good luck,
Dan

Dan brings up a good point. It's been a long time since I opened an 8640,
but being a very clean RF gen it has loads of shields and lots of pages of
documentation to cover the loads of modules contained in the box.
Troubleshooting will be hard, but not insurmountable. Even after all
these years, it is probably one of the best rf sources around for doing
off channel measurements. It is definitely worth the effort to fix unless
you want to buy an 8642, which costs more than what I paid for my house.
:-)

=====
No flaming intended ,but we talk here about Li-ion not NiCad or NiMH
batteries .
Li-ion batteries need a different charging procedure and the MAHA -C777PLUS

charger does just that ,in addition to NiCads and NiMHs.

try here:
http://www.logsa.army.mil/etms/find_etm.cfm
you'll find two file:
the first is service and user manual (11 Mbyte/ 409 pages)
the second is the part list (some Kbyte and 40 byte)
bye

The diode is supposed to conduct and blow the fuse in the negative
lead when polarity is reversed, thus providing the protection. The
diode alone will not provide any protection. If both fuses are good he
will be lucky to not have any damage.

Hi Talino,

Thanks for the url - I would love to get the service manual for the HP8640.

Unfortunately, the site requires browsers with 128bit encryption. I use Explorer 5.0 which has 128bit, but it doesn't pass their browser check.

Can you give the url for the HP8640? Maybe the site will allow me to download it directly.

If not, is there anyone with a wideband connection who is willing to email me this file? I would sure appreciate it!

73, Mike

If I remember correctly, the 8640 manual was about 5 cm thick and was more
than just one manual. Try the obvious stuff first and worry about a
manual later, although it is nice to have.

I understood that he wished to do it with discrete components rather
than IC's for a reason or another. Remember the MC1330 a quasi
synchronous detector, tried it for AM, but no success, better was
TDA1576, TBA120/SN76660N and MC1351 (and NE/SA604/614) on 455kHz.
The true synchr. detector requires a PLL tuned VCO. Believe ARRL
handbook shows such circuit, but for 455kHz, but for TV the IF is
33.4-38.9MHz (32.9 in England) and 38.9 is the VISION carrier freq.

Source record: 40733

wonder if somebody has any experience why frequency jumps, seems to be a problem for FT-901 as well as FT-902. A suggestion is bad decoupling capacitors, but if somebody has particular experience in curing just this type of rig it woul save me lot of trouble

It is possible to use the memory and lock it to a steady frequency, so it might indicate the problem is found in the VFO

==========
A common AM radio on a chip is the MK484 . It is a 3 terminal device looking
like a plastic transistor
Here in the UK the G-QRP Club are selling the device for equiv. US$ 1.50 a
piece (including a circuit diagramme).

I am sure it is available in the USA ; suggest you check with Digi-Key or
Mouser.

My reason for using discretes is that I want to retain manual IF gain
control, rather than use AGC. The TDA (and other) series of ICs made for TV
all use synchronous detection but I have not yet found an IC where I can
bypass the in-built AGC and control IF manually. If anyone knows of one then

my problem is solved.
I've checked my various ARRL handbooks, (latest is 1992) but can find no reference to synchronous detection. My thoughts were running along the same lines, PLL, VFO running between 32 and 39mHz.

Chuckles
Because slide rules were a very simple, yet powerful tool. And, once you learned, were really simple. I work in a computer science department, with computer scientists. Don't get me started... We don't want to go there. And I am a gentleman and would prefer to pretend I did not know that kind of language as I would, no doubt, cut loose with.
And, with deepest respect to the gentleman who posted the link to the slide rule page... Thank You! Thank you very much!
And I have placed my old trig Pickett in my desk drawer, where I can get hold of it when I need it.
Well, I need to sit down and put together the lighting detector as was in a QST a bit back. I finally got the few parts I could not find in my collection of "Junque".
Paul.

Sorry - Forgot to mention my current IF setup is MC1330 gain controlable IF
amp followed by MC1350 amp/detector. Looking at the internal circuit for the
MC1350, it looks like a normal envelope detector.

> Seems you're saying there's a definite explosion hazard involved with

Yes, that is correct. I'm surprised you were able to get LiIon cells.
Manufacturers generally don't want to sell the batteries without reviewing
the protection circuitry to avoid liability. These things are nasty, and
manufacturers recommend 2, preferably 3, independent, circuits to avoid
overcharging.

Explosion is perhaps a bit strong of a word. The battery burns with an
extremely hot flame which emits toxic gasses. Water will make it worse, and
CO2 or dry power extinguishers won't touch it (although they won't make it
worse like water). One manufacturer suggests that a CO2 extinguisher will
at least cool the surrounding area preventing the fire from spreading, but
without the appropriate gas mask, that's a sort of academic concern.

Don't confuse lithium ion cells with lithium primary cells which are
relatively tame.

..

Paul:

Heh, heh... no offense meant.

Some of my best friends are computer scientists.

I've noted over the years that computer scientists just don't seem to know very much intimate detail about computers. It seems, judging from his famous quatiation about astronomy and telescopes, that one of the most famous computer scientists, E. Dijkstra has noted the same... I've often thought that it is too bad about that misnomer created to define the "computer scientist", which unfortunately leads one to believe that such folks are experts on computers, but then what else could we have called them! Algorithm scientists, programming scientists, data scientists, what?

Slide rules are computers, they are extremely efficient analog computers, and of course there were electronic analog computers in wide use long before the advent of the digital computer and modern computer science.

Since I was helping with the design, development and manufacture of analog and digital computers way back when there were hardly any computer scientists, my perceptions of that particular kind of "scientist" might be tainted a little by my personal experiences with the first few whom I encountered. Hence my sceptical nature regarding the intimate familiarity with computers of modern computer scientists.

BTW... From appearances alone... it seems to me to be so much easier to "admire" the clearly obvious ingenuity present in a handsome slide rule than a digital computer. You simply can't see the "ingenious bits" in a digital computer, all you see is a keyboard and a screen... it looks sort of like a teletype terminal.

Best,

Hi Richard,
re the LOGSA site, a few things before downloading a new IE (which probably couldnt hurt anyway)

1) This site uses a security certificate, and i'm not sure you can go direct to the ETMS page without going through the front door if you've never been to the site before.

2) If you are using a firewall, check it's settings to make sure the certificate can get through.

I've downloaded the 8640 manual from there, not the greatest, but readable.

Cheers
Greg

It just suddenly stopped. No output
Freq Indicator 000000000Hz. Metering and other functions appear OK
Any ideas about what happens to these?
I understand they are fairly complex.
I dont have a manual - guess I will look on E Bay

Richard

No, inside the MC1330 is a balanced modulator, with the input signal
going directly to one input, and going to the other after some limiting.
In effect, a constant amplitude signal at the carrier frequency is
mixing with the incoming signal, providing you with your baseband
signal.

If you have the datasheet, look at it's internal circuitry, and then
compare it with that of the MC1496 double balanced modulator.
Q8, Q9, Q10, Q15, Q16, and Q17 of the MC1330 are in the same form
as the basic DBM in the 1496.

The MC1330 has some extra transistors, for the input, limiting,
and output buffering, and it's configured specifically for this
purpose (and doing away with the many components that the 1496 requires)
but the scheme is no different than a circuit from 1970 in a Ham
Radio article (it might be in an application note somewhere) for
using the MC1496 as an AM detector. The author said that a limiter
wasn't even needed, because one set of inputs limited easily.

But as Jan-Martin says, this will give a "quasi-synchronous detector".

Your AGC problem seems to be due to looking at ICs that give a lot
of integration, ie not just a detector but an IF amplifier and AGC.
I think there were some older devices intended for tv use that
were less integrated, but I suspect they aren't being made any longer.

What you need is a PLL with an extra balanced modulator. Over thirty
years ago, Signetics had a line of analog PLLs intended for signal
processing use, and at least one of them had the extra balanced modulator
needed for AM synchronous detection. It was either the NE560 or NE561.
But they weren't up to the desired frequency.

So you'll have to dig up some sort of balanced modulator, an MC1496, an NE602, a diode ring mixer, or any of a number of other possibilities. And then a PLL that will work at the desired frequency. This sort of scheme has been described plenty of times in the literature. Look at TV ICs that have synchronous detection, such as the National LM1823 or the Motorola MC44301, for the basic idea.

I don't know if it's still available, but the NE564 is an analog PLL that I think works at the needed frequency.

The original article "A Synchronous Detector for AM Transmissions" by Jukka Vermasvuori OH2GF appeared in QST July 1993, pages 28-33 and it may have appeared in some later ARRL handbooks.

It has a VCO built around the NE602 feeding the quadrature input of the NE604 IF amplifier/FM detector through a 90 degree phase shifter. The 455 kHz IF signal is going through the NE604. From the NE604 audio output the loop error voltage is connected to the NE602 VCO and it is also used as the in-phase detection of AM signal coming from the IF amplifier in the same NE602.

In a synchronous detection, you need a phase detector, which is running in quadrature with the received carrier (in this case in the NE604) and an other detector running in phase with the received carrier the recover the signal (in this case in the NE602).

I have no idea if the NE604 will operate at 40 MHz, so you have to check that. In addition to changing the VCO frequency, you would also have to change the loop filter. You might also put some narrow band filtering in front of the NE604, but this should have a linear phase response, otherwise the in-phase detector would not be in phase any longer and the recovered signal may disappear completely if the phase shift in the filter is some odd multiple of 90 degrees.

It should be noted that at least in Europe on VHF Band I, the TV transmitters are not at the exact frequency but spaced by some submultiples of the horizontal sweep frequency (IIRC multiples of fh/12) to avoid interface problems, thus the PLL lock range should be at least as big as this. If the TV-tuner synthesiser step size is 62.5kHz, the lock range should be larger than this.

One other source of AM/FM ideas could be the application notes for the Signetics NE561/562/563 PLLs, but these have long been out of production. If you find such chips, you have to use the VCO range extension trick by connecting two resistors to ground from the VCO

capacitor and the upper frequency range will extend from 30 MHz to 60 MHz.

Firstly - apologies for wasting everyone's time. I'd incorrectly stated that I was using an MC1330 voltage-controlled amp. My previous post should have read "..using an MC1350 voltage controlled amp followed by an MC1330 (A2P revision) detector". After reading Michael's post, I went back and checked the data book, to find I'd missed the fact that the MC1330 is indeed a quasi-synchronous detector. RTFM pays....;-> The main reason I want to use synchronous detection is the improvement in s/n ratio on weak signals when compared to a classic diode envelope detector. My understanding is that the MC1330 should be an imporovement on this. The question now is, is it worth going to the extra trouble to build a 'proper' synchronous detector using PLL, mixer etc ? Does anyone have any idea what the relative merits of the 3 systems are in terms of dB-s/n ratio on weak signals are ? - Thanks again for your patience.

They are far more elaborate than a "fuse".

Usually comprise under/over-voltage and excess charge/discharge
current sensing. Open ccts a series FET in the event of any of the
above conditions. Usually also activates on mismatched cell voltages.

Li-Ion cells require these measures for YOUR safety. Anyone who
operates them outside the 'envelope" is running the rsik of
catastrophic cell failure at the very least.

Prot modules are almost invariably configured for the number of cells
in the pack, so a 3-cell module cannot be used with a 2-cell cut-down
version of the same pack.

If you are using a wideband scope I would worry about the triangular wave. Put the scope in DC couple and use the ground input to set the 0v level. The clock should show a swing from ground to 5vdc and it should be square. If you are using a 10:1 probe, also go through the trouble of making sure that it is compensated properly. Use the calibrator output and set the timebase accordingly, and adjust the probe's trimmer until you can see a good square wave. Then you can measure the clock with some certainty. You can verify the scope also with the DC measurement of voltage using a DMM or even an analog meter, for that matter.

3042. Re: Homegrown Li-Ion battery pack for FT-50

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-14 12:19:08 UTC
From: Markus Baertschi <markus@markus.org>
Message-ID: <MPG.1814cdd8579d2987989690@News.CIS.DFN.DE>
Source record: 40755

Just some clarifications:
The original Laptop battery had 6 cells. They were connected in parallel
and serial to get from 3.6V/1.8Ah to 10.4V/3.6Ah. There was a quite
complex prtotection module in the pack. As my configuration is very
different I did not attempt to use it.

For now I've replaced the 8 NiCd cells in my NBP-41 (7.2V 600mAh) with
two cells (fits mechanically) and did charge it with my slow Yaesu wall
charger. This works fine so far, the pack did not get warm, even after
20 hours of charging. The Maha charger is on order and will take another
week to get here.

There is a fair amount of free space in the case and I could easily add
an protection module. Where can I find corresponding schematics ?

3043. FS: Old Radio Books

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-14 13:24:24 UTC
From: oldbooks78@aol.com
Message-ID: <20021014092424.20410.00002039@mb-ch.aol.com>
Source record: 40758

I currently have for sale the following old radio-related books. Postage is $2 for the first book and $1 for each additional item (Media Mail within the US, at cost elsewhere). The books are:

Graham, Frank D. "Audels Radioman's Guide, Modern Radio Practice" Theo. Audel & Co., 1932. Tan cloth covers over flexible boards. The book is about 250 pages in length (pages are numbered oddly, making a total count difficult). A nice early vintage radio book, illustrated throughout. Clean with no page tears or pen marks except for a gift inscription inside the front cover. Cloth covers show some spotting and light staining from age, but not bad at all. Available for $12.

ARRL "The ARRL Antenna Book, 13th Edition" American Radio Relay League, 1977. The 336 page softbound book is in about very good condition. Clean with no page tears or pen marks. The covers show a bit of wear from previous use, but not bad at all.A comprehensive treatment of radio antennas. Available for $7.

Jordan, Edward C.; Paul H. Nelson; William Carl Osterbrook; Fred H. Pumphrey; Lynne C. Smeby; and W.L. Everitt (editor) "Fundamentals of Radio" Prentice-Hall, 1944. The 400 page hardbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Gray cloth covers with some minor spotting on the front cover, otherwise nice. A nice early radio related text. Available for $10.

Siegel, Hy "All About CB Two-Way Radio" Radio Shack, 1976 Soft Cover. The 112 page softbound book is in very good condition, clean with no page tears or pen marks. Nicely illustrated. Available for $5.

US War Department "Technical Manual - Radio Fundamentals, TM 11-455" U.S. GPO, 1941. The 140 page softbound book is in fine condition, fresh and clean inside and out except for a previous owners name on the front cover. A nice WWII vintage radio manual. Available for $10.

Federal Telephone and Radio Corporation "Reference Data for Radio Engineers, Second Edition" Federal Telephone and Radio Corporation, 1947. The 322 page hardbound book is in good+ condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover. "The present edition has been greatly enlarged and a subject index included. Chapters on transformers and room acoutics have been added. The material on radio propagatiion and radio noise has been revised. The data on cathode-ray tubes have been considerably expanded." Available for $8.

Everitt, William Littell "Communication Engineering" McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the

science of the radio. Available for $9.

Measurements Development Laboratory of the Sperry Gyroscope Company "Microwave Transmission Design Data" Sperry Gyroscope Company, 1944. Publication No. 23-80. The 215 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Originally issued during WWII as a "confidential" document. Chapter topics include General formulae for concentric lines; Attenuation in concentric lines; Reflections and impedance matching; General formulae for wave guides; Attenuation in wave guides; Reflections and impedance matching in wave guides; Wave guide tees and bends; Wave guides filled with dielectric material; Dielectric material: Cavity resonators; and Measurement techniques. A neat early book on ultra-high frequency radio waves. Available for $10.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

I'm reminded of a posting a few years ago in which the poster, a young lady, stated that she had a masters degree in Computer Science but had never seen inside a computer. She was wanting advice on how to proceed to gain some inside-the-box knowledge.

Then there was the more recent post by someone here, I think, about the young lady with a Masters in EE that had never had a soldering iron in hand and had no idea how to use one. She had never attended a lab class.

You gotta wonder just where all this is going.

Dear all

Thanks for all the helpful info
In reponse to various posts

The INT/EXT switch is INT :(

The timebase out next to the INT/EXT switch shows a triangle wave about
1.75V P-P period 0.2 uS ie 5 MHz

The display registers and the various indicators appear to have power so I
presume the power transformer is OK

I tried accessing the manual site that was suggested but I also got a
browser error message - guess I wil have to download another version of IE.

There is no signal discenible on on external receiver

The counter wont work on external mode

I would be grateful any further ideas.
Thanks for your tolerance!

Richard

Seems you're saying there's a definite explosion hazard involved with Lithium Ion batteries. If so I'd like to know more, since I've begun to use them for some applications and was not aware of any hazard other than to the batteries themselves.

I recently bought a set of four 1800ma lithium AA cells with a matching charger for use with my digital camera. Later I picked up another set of four
rechargeable AA's that are marked 1600ma NiMH as a spare set. I've been charging them in the same charger that came with the lithium ion cells. I noticed they seem to get somewhat warmer while charging. Am I screwing up or is this a workable situation? If the NiMH cells shouldn't be charged in the LiION charger, can they be charged in an older NICAD charger?

Can you charge Li Ion batteries successfully using a low rate of charge with an adjustable power source with a charging current level meter, say at a 5 or 10% of the full current rating? Individual cells? How about the NiMH units? This works well with the older Nicads. Such info seems to be hard to find in any one place even on the WWW. A link or URL to such a site would be nice.

Your answer will be much appreciated, probably by several of us here.

Well, it is poor training to never learn the hands-on, but out in
large companies, it is often the case that engineers never do any
hands-on work, and in some situations, are prohibited from doing any
by company policy or union rules.

There is an expression for those electronics engineers who have never
done any actual soldering; "doesn't know which end of a soldering iron
to hold".

Hi Richard,

You didn't mention if it was the 8640A or 8640B. If it is the B version,
and you are still looking for the manual, I just downloaded it from here

http://www.slack.com/david/pdf/HP8640B.pdf (11.2 meg)

It covers the following serial number prefixes:

1324A, 1229A, 1244A, 1245A, 1246A, 1249A, 1251A, 1303A, 1310A, 1313A,
1316A, 1322A, 1323A,
1327A, 1332A, 1333A, 1339A, 1342A, 1345A, 1350A, 1401A, 1404A, 1404A,
1405A, 1406A, 1416A,
1419A, 1423A, 1429A, 1431A, 1435A, 1438A, 1440A, 1442A, 1501A, 1506A,
1513A, 1515A, 1519A,
1520A, 1524A, 1526A, 1530A, 1532A, 1534A, 1535A, 1538A, 1542A, 1543A,
1544A, 1545A, and
1552A.

Hi Markus,

There should have been a "module" in the original laptop battery pack, take that out and use it.

I didn't the same thing as you several years ago, took a pack apart and wire 4 in series for my FT-530. For charging I just connect the pack across my station battery over night and let it take what it wants. It may not be "safe" or "smart" but it works and never a problem.

The Phillips TDA1072 and the TDA1572 are both current products. The 1572 is used as the I.F. subsystem in both the AOR7030 series of receivers and the Linn Kudos FM/AM tuner. All functions, including detector and AGC are on board. The difference between the two is that the 1572 has a buffered 50 Ohm I.F. output.

After repairing some boards that a couple engineers screwed up, I
wished they didn't even know what solder was. Others are ok, but a few
think their piece of wallpaper means they know EVERYTHING.

3056. 50's Schematic Wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-14 17:49:55 UTC
From: Al <afjay*@earthlink.net>
Message-ID: <afjay*-73552C.13495614102002@news.bellatlantic.net>
Source record: 40769

When I was 15, in the mid 50's, I built a shortwave converter. I still have it and it still works. But I don't have the schematic. Can anyone help me find it? I think the plans may have come from either the ARRL Handbook or else from Radio/TV/Electroics (if that is the name).

Details:

It uses two 6J6s and a third tube I can't make out.
One selenium rectifier.
One band set capacitor and one spreader capacitor
One antenna tuning capacitor.
It is a hetrodyne that converts the HF bands to the AM band.
It has 5 sets of coils to set the bands.

Thanks in advance.

Al

????
I mentioned MC1351 - it is quite different from MC1349 and 1350, a
problem with TDA1576, TBA120, SN76660N, MC1351 and SA604, NE614 is
that none would operate properly on 30-40MHz, so you might have to try
SBL-1 or MC1496P

Both the MC1330 video detector and MC1350 (plastic DIP version of MC1590 differential RF amplifier with AGC) were intended for TV receivers when designed back in the early 1970s. The MC1330 has an internal balanced modulator and an externally-tuned limiting amplifier that drives the balanced modulator. A key to proper use of the MC1330 is getting the impedance of the external tuned circuit within the proper range so that the internal limiter-modulator-driver operates properly. In trying to use the 1330 below 30 MHz or so, most try to "tune" it with tube-type impedance LC circuits and the result is less than good. See old detailed Motorola spec sheets for information if they are to be had (personal copy of Motorola App Note long gone)

I used the MC1330 in an 8-channel R&D airborne application at RCA Corporation in 1974, detecting RF pulses of 1 uSec width at carrier frequencies of 55 to 63 MHz. Use was dictated then by physical space available and sensitivity. Dynamic range of 35 db easily achieved with good input-envelope to output-video fidelity, a necessity for post-processing of video.

A conventional diode AM detector does not, cannot provide fidelity of modulation at low levels due to diode characteristics operating below the knee of diode forward conduction. See any simple DC forward current v. forward voltage plot. Above the knee a diode detector behaves like a power supply rectifier, output following the peaks in RF envelope inputs so high-level AM fidelity is good. At low signal levels a germanium diode might be better than silicon because the knee of I versus V has a lower voltage.

A "synchronous detector" is exactly the same as a "product detector" with a locked-to-carrier "BFO." Both do demodulation through mixing the AM-ed RF components (carrier resupplied through a locked oscillator or through a tuned limiter)...with the modulation audio output a result of RF mixing. Fidelity is excellent at all levels since the output is not dependent on any "peak-riding" effect of a single diode detector. Demodulated output is really the relationship of the signal's RF components very close to what they originally were.

An advantage of the synchronous detector in HF reception is the internal carrier resupply constancy overcoming some of the HF selective fading effects of the carrier. That results in a better-sounding AM signal (particularly with SW BC) on paths with fading of up to 30 to even 40 db. AM sideband components fade, of course, and those are apparent, but carrier fading is more apparent with conventional diode detectors due to the low-level semi-logarithmic output response.

A disadvantage with synchronous detectors is a "capture effect" of close-in signals unlocking the carrier resupply frequency from the desired. The capture effect is similar to that in FM where strong near-frequency signals take over the receiver's limiter action. A way out of that is to use bandpass filtering ahead of the carrier resupply subcircuit. My RCA application had SAW filters ahead of the MC1330 detectors, about as close to an ideal "brick wall" filtering as possible.

Any synchronous detector should be able to receive SSB or DSB AM with the carrier resupply having its frequency lock disabled (allowed to free-run stably). That puts it into equality with nearly all conventional SSB detection methods...recovered modulation follows the original AM RF components with good fidelity, even at low levels.

SW BC receivers tout the "synchronous demodulator" as a buzzword to sell products. HF SSB receivers have had "asynchronous demodulators" for years with good success...known under very old (misapplied) names of "product detectors" and "BFOs," names that did not get picked up or last long by other, non-ham HF radio users :-)

A good "product detector" is just a MIXER, a switch of sorts, being switched at a high level by the BFO or carrier resupply oscillator at the back end of the IF strip. Its output is the algebraic difference of the RF/IF components, the sidebands against the resupplied carrier. Demodulation linearity is that of the mixer itself...usually excellent with a strong local oscillator (the "BFO" or carrier resupply oscillator). This remains true even with old single-diode detectors using a BFO since the BFO literally turns that diode on and off. Try that on any CW receiver, tuning in an AM signal zero-beating with the carrier.

As to receiver sensitivity improvements, I would suggest going first to the front end and improving that. Nearly all modern HF receivers are now very close to the Shannon Law limit. For demodulation fidelity,

that would be in the detector or demodulator at the end of the IF.

Locking the carrier resupply source (BFO, limiter, PLL, etc.) to the incoming carrier is a separate task and more complicated than it appears. The carrier, or reduced carrier with suppresed-carrier SSB, is subject to large changes in signal amplitude. It might also have very strong adjacent-frequency signals of many kinds. Those must be simulated on bench testing to find out effectiveness of the carrier resupply subcircuit. Not easy and not all App Notes mention the problem much...but it is a ripe area for experimentation.

The easy way out is to just use present-day SSB demodulation techniques, using the most linear mixer subcircuit for good demod fidelity. The carrier resupply source need only be stable (crystal oscillators good for that, heh heh) and the tuning LO needs to be stable. "Carrier lock" would then be up to the knob-twister.

Note: It IS possible to build a carrier resupply subcircuit that CAN lock onto just the sideband products of DSB AM in a total absence of received carrier. Unfortunately, the analysis of such a problem is a whole new kettle of worms, going deep into modulation theory. I don't think it could be done with SSB no-carrier signals, but haven't looked into that. DSB AM detection with no carrier resupply lock is an interesting area and has been tried several times, producing a weird sort of "stereo" effect with each ear listening on different sides of the carrier. The brain and its own hearing circuitry can then join into the full reception loop. :-)

Believe the problem with MC1330 is that it hasn't much limiter, and
you probably won't find many devices operating on 40MHz. Another
device we used for SATTV demodulators on 70MHz is MC1357P, but
probably older device than MC1330. Believe it is another manufacturer.
Have seen an application where only the limiter stage of MC1357 was
used, it is hard to find a good and inexpensive limter on higher
frequencies, MC1356P is another suggestion, it has simple limiter
stages - no darlington-connected limiters, but Motorola doesn't tell
any information about upper frequency limit. Modern devices are
designed for low current consumption and as such low frequency limit.

If youreally decide to make a proper synchronous demodulator limiting
is a nuissance

>The question now is, is it worth
>going to the extra trouble to build a 'proper' synchronous detector using

have no figures

NE564 also worked for FM on 70MHz, but will it work for VSB-AM?

what is SRF ?

It was quite easy to calculate the capacitance, just to remember the
math ..., as LA7MI points out
capacitance on 120kHz is 4 times the capacitance on 240kHz, and the
calculation is
(50 + x) * 4 = (800 + x)
3x = 600
x = 200pF

splendid, but the term "winding pitch" doesn't really makes sense when
you try to crosswind it, I later learnt that type 38 from Electronics
World august 2002 was better, so perhaps it wasn't so good idea to use
cross winding, mine has stray capacitance of 200pF while the described
antenna has 70pF, and lower stray capacitance gives higher Q.

An example using the program is shown below (works for win98):

L Length of one side of square frame, mm 1000
N Number of turns of wire on the frame 30
D Diameter of wire, milli-metres .... 1.8 .
R Ratio of (winding pitch)/(wire diameter) .. 2.00
F Frequency, kilo-hertz 136

Inductance .... 1973.9 micro-henrys
Inductive reactance .... 1687 ohms
HF loss resistance of wire . 4.32 ohms
Radiation loss resistance .. 0.00 milli-ohms
Self-resonant frequency .... 1.1 mega-hertz, approximately

Total capacitance required . 694 pico-farads for resonance
deduct stray capacitance 10 .. ..
Setting of tuning capacitor. 684 .. ..
Approximate coil Q 391
Receiving sensitivity ...... 66 decibels below 1/4-wave
vertical

Width of winding .... 106.2 milli-metres
Total length of wire .... 120.00 metres

Impedance seen across loop . 658.7 K-ohms, when tuned to
resonance
Impedance seen by Receiver . 0.7 K-ohms, via 1-turn
coupling loop

It's a fairly standard 723 regulator Richard, with the big pass transistor on the back panel. The 4.7 feeds the fan circuitry. There is a big 0.68 Ohm current limiting R down near the bottom of the card, between the pass emitter and ground. I don't see any 0.91 Ohms. Edge connector 12 to C of the pass transistor, 13 to B and 11 to E. Q3 1884-0012 is a crowbar. There is a 2 amp fuse on the board, directly below TP2.

Many of the first gadgets using LiIon batteries caught fire and
burned and so the mfg's did recalls. This is because LiIon batts
tend to fail catastrophically when abused.

> I recently bought a set of four 1800ma lithium AA cells with a matching

Rechargable Lithium batts in a AA voltage and form factor??? Where ???

The lithium cells with a 1.5v cell voltage as advertised by
Energizer (e2), etc. are not rechargable.

Rechargable lithium-ion cells have a 3.6v cell voltage.

> rechargeable AA's that are marked 1600ma NiMH as a spare set. I've been

> charged in the LiION charger, can they be charged in an older NICAD
> charger?

If the older charger supplies no more than 160ma then you can charge
the NiMH with it for 14 hours or less (if they start getting quite
warm, they are fully charged).

If the charger supplies more current, you risk the health of your
NiMH cells.

The NiMH end-of-charge detection is more difficult, and most NiCad
fast chargers do not do a good job with NiMH.

Or better, put a pullup on the inputs, and use the switch to ground
the input. Switch closed==0, switch open==1.

When plotting and using the regression analysis plot 1/(2*pi*F)^2, not
1/F^2. Sorry about the error.

When I redid the calculation got 208.6 pF +/- 23 pF.

At Staples Office Supply. Four 1800ma AA's with their charger was
$29.95.
They're quite good .

Thanks for your response. It made me go take a very close look at
exactly what I have, on which device, and exactly what each is. I've got
a new cellphone and a fairly new camcorder, both of which use lithium
ion rechargeable packs. I also have a fairly new laptop computer that
came with a lithium ion battery pack. I would have wagered that the four
individual cells that came with the charger that I got when I purchased
the digital camera were also marked 'Li ion', but I see they are NiMH,
as are the other lower-current backup set. I was wrong. I *don't* have
any individual lithium ion cells, they're all NiMH.
Looks like that's a good thing. Thanks again. And my apologies for the
mistake. Darn, that print on those cells is small! <g>

Note that they are NiMH, nickel metal hydride, cells rather than
lithium ion.
I misread the labels on them. z

Did you want this to be all-mode? FM only? There was a design back a couple
of years ago in QST for a digitally controlled one.

Do you want your radio totally analog, or do you want a cpu controlling
things?
thanks, John.

The scope is a 100 MHz Tek which is OK and reads the same on both channels.
The DC level is 0 ie the waveform is symmetrical around GND
It would make sense that the timebase is not working as the counter doesnt
work either.

Having opened the beast up - the LED on the -5.2V/Fan supply board is not on
There are a few components which have got hot - one is a 0.91 ohm (?series
regulator) resistor which reads correctly
and a 4.7 ohm 1/4W which reads 15 ohms. Replacing this makes no difference.
I presume one of the power supply loads is a short circuit.
I will await a manual unless anyone has any ideas.
It sure is a beautifully engineered piece of equipment!

Thanks

Richard

If they are Li-Ion then you should seriously consider yourself (a)
lucky and (b) at risk that this luck won't last.

Overcharging presents a serious risk to the cell integrity and its
surroundings.

Normally Li-Ion manufs recommend a current-limited constant voltage
charge regime. This applies typically 4.2V/cell and regulation is
required to be tight - one company's prot modules open at 4.25!!!

Because of the serious implications of overvoltage, PM's also
generally include cell voltage mismatch monitoring, so that applying
4.2V/cell to a series string doesn't risk pushing any one cell over
the edge.

>with an adjustable power source with a charging current level meter, say
>at a 5 or 10% of the full current rating?

NO. These cells need to have the applied VOLTAGE controlled fairly tightly. They are not able to absorb excess coulombs by way of recombination as do NiCd/NiMH types. they also have a VERY HIGH coulomb efficiency - typically better than 97% compared to 65% for Ni types. (Coulomb efficiency rates the amount of charge obtained on discharge as a percentage of what was put in during the charge phase).

>Individual cells?

Same story.

>How about
>the NiMH units? This works well with the older Nicads. Such info seems
>to be hard to find in any one place even on the WWW. A link or URL to
>such a site would be nice.

NiMH and NiCd share a lot of common attributes. One is their ability to accept long-term "overcharge" at low rates without serious harm. As this rate increases, so does the heat dissipation and temp buildup - which is the main cause of cell failure in Ni types. If the rate is civilised (e.g C/50 or so) then indefinite overcharge appears not to present a risk to Ni types.

Matt:

Cost is not usually the reason for homebrewing ham radio gear these days. Unless you have a well stocked parts room, you will spend more buying parts to build something than you would buying the item ready made. Most of us who build equipment do so for the fun of it, not to save money. That doesn't mean you can't save money by building things yourself, especially when you are an adept scrounger and flea market browser, but often you spend more.

And when you said you wanted to build a transmitter, did you mean transceiver? A transmitter needs a receiver to be useful, and that adds to the complexity and cost of your project.

Also, unless you have some experience building, troubleshooting and tuning VHF RF devices, a 2 meter transmitter is a big project to start with.

You might look at some of the kits available from TenTec or Ramsey as an alternative to scratch building.

Good luck,

Roger K6XQ

For starters, check out the .pdf on the Maxim MAX1737 for an insight
into the manuf-recommended " & feeding" of Li-Ions. A good chip, we
use it in our commercial/industrial charger designs. (NO, we don't
do domestic/consumer).

Protection circuits - I have a huge# of .pdfs and the like we sourced
over a period, but unfortunately the originators don't provide the URL
in the document.

Look at powerlogics.co.kr

A Google search on: lithium ion charge controller
will turn up more C&F stuff, while searching on:
lithium ion protection module

should be useful - that's where we started.

Also search on
PLM-4005
SC4000S

as some example prot modules.

For the cells, maybe search on: lithium 18650

Hope this helps.

Ian,

I'm not an expert by any means on this gen, but have used it for 25 years. Someone correct me if I'm wrong, but the HP8640B is frequency locked and not phase locked. That's why you have to constantly have to retune it in unlock mode and then go back to locked. I'm guessing, not knowing what the dither is, that the dither is caused by the +/- half digit effect of frequency locking. This is due to the uncertainty of the time gate drifting in and out of phase with the signal. Like I said, this is a guess on my part.

BTW, I think that the HP8640A is not locked at all. It's just a very clean, stable, tunable, cavity oscillator rf gen. Both of these models are works of art, but you must remember, they came from the HP608, which literally was built by machinists and other craftsmen. Brother! What a boat anchor! :-)

This is a great time to be homebrewing mics. You can make one that is
super using a really cheap electret cartridge. They are flat from DC to
blue light and they don't "colour" the sound. If you like shaped
frequency response, you will have to do that after the mic. The only
caveat: when soldering these cartridges little heating of the cartridge
can be tolerated. Too much heat and the dielectric of the element no
longer has a built in charge and there is no audio out of the mic. A hot
(800 deg) iron with a small tip and fast hands should be used for
soldering. A clean tip and some flux on the terminals may also help to do
a quick clean job. If you're having trouble and you're soldering a small
cartridge, go to one that's larger, they are a little more forgiving.
Also, get the cardioid mic if possible and don't plug up the port on the
back of the mic. It will then be non-cardioid or omnidirectional.

Hi Jan,

SRF is short for self resonant frequency. It's the frequency at which the
inductor ceases being a coil and crosses over into the realm of a
capitor. In the cross over, there's a point where it is neither L or C,
but R. The coil is a one component tank circuit at this point also,
comprised of the inductance in coil its series resistance, and the
parallel capacitance of the winding to winding capacitance totalled up.

It looks really neat on a vector impedance meter because you can actually see where it is resistive only (it's narrow though).

Matt

I applaud you in your intrest in building a 2m xmtr. Once you have a schematic check on the availabilty of parts and their cost. You may be able to scrounge some parts for free. The ones you cant look at the price closely. You can buy a used handi talkie at a hamfest for <60 bucks. I saw 2 radio shack htx202's at the last hamfest both for 50.00 and both worked.

Best of luck on your project though.

Rich

Thank you very much. I expect that info is out there somewhere buried
in reams of dry reading, but I hadn't came across it yet. Now I know.

Hi.

Does anyone know a source for the NE568 (or SA568) PLL chip in the UK ?

If not then maybe a similar chip that can work around the 30 to 100MHz region
that can act as a wideband FM video demodulator (and possibly modulator).

Need to find a chip so I can send good quality video down coax along with power.

Regards ... Clive

RS Components stock the NE564D (At least the Australian branch does) - I have a data sheet for the NE564 that puts the max freq @ 50MHz. According to data in the RS catalogue (skimpy) the D version may be as low as 500KHZ. I've used the 564 for FSK demodulation with a 50MHZ carrier and it worked well. Should be OK for your app - hope the D version is suitable.

Thanks for the confirmation. If it was a B-model, that would have been
my guess, and I'd have expected the dither to disappear on switching off
the locking.

But...

>BTW, I think that the HP8640A is not locked at all. It's just a very
>clean, stable, tunable, cavity oscillator rf gen.

That's the model I have, so there's some other problem. As far as I can
guess, it could be in either:

* The VFO itself... oh boy, I hope not!

* The power supply... easiest to fix, so it's sure not to be that...

* The electrical fine tune / FM side.

Unfortunately I can't find an 8640A manual at the US MIL site - any
ideas, please?

>Both of these models

Power supply ripple? Oven going on and off? Noisy contact?

I don't know if we have the manual any more. I will ask next time the person
who knows is in.

Mike

> splendid, but the term "winding pitch" doesn't really makes sense when
> you try to crosswind it,

==========

What do you mean by "crosswind" ?

"winding pitch" means exactly what it says - it is the distance between the centres of adjacent wires in a solenoidal or helically wound coil.

If you wind coil turns over each other (crosswind) obviously it greatly increases self-capacitance. For a given number of turns it also decreases coil width (or length) and so increases inductance somewhat. You are not talking about the same antenna.

It should also be said, contrary to popular (guru) belief, an increase in self-capacitance does NOT result in a decrease in Q when a coil is used in a parallel tuned circuit. Circuit Q is degraded ONLY when a coil is used in a SERIES tuned circuit.

For example, in a tuned-anode tank circuit or receiver input circuit, Q is not affected by self-capacitance. But when a loading coil is inserted in an antenna the Q can be seriously affected and power dissipated in the loading coil will increase.

But to return to correctly designed LW and MW frame antennas, the effect of self-capacitance is to VERY slightly reduce the setting of the variable tuning capacitor. If a coupling coil is used then that may also slightly increase self-capacitance depending on location. If you lean the antenna against a wall, get off your chair and stand alongside it, or rotate it by 90 degrees, self-capacitance will change again. But nobody will notice any difference. <grin>

Yours, Reg, G4FGQ

Sounds more random than that.

>Oven going on and off?

No oven!

>Noisy contact?
>
That's more like it - more specifically, a noisy contact that can cause
FM but (as far as I can hear) not AM. When I can't tolerate it any more,
the FM circuit will be the first place I'll look.

I downloaded the 8640B manual, but the FM circuit is one area where the
8640A is definitely different - because the B has the lock facility but
the A doesn't.

>I don't know if we have the manual any more. I will ask next time the person

Put tube in refrigerator for 30 minutes or so. Remove tube and "huff"
on it with air from your lungs. Oftentimes, the condensation will
enhance the writing on the tube enough that you can make it out.

If you shop around, you should be able to find a decent HP 141T spectrum analyzer system that goes to 1250 MHz for under 500 dollars. A far cry from the SAM and the kits.

Got the reply from LA8AV whom had serviced many such rigs,
he says that 90% of the cases of instability is caused by bad
edge-connectors and it is solved by cleaning the board-edge with
isopropanol (what you use in your car to clean windscreen), only in
one case was bad solder in the VFO - and it is a terrible job to
removed the box

From: scott <acepilot@bloomer.net>
Message-ID: <3DAC9627.EF4401B6@bloomer.net>
Source record: 40657

Well, if you build a transmitter, I assume you need to build a receiver as well? Or are you listening on a scanner? Either way, it may still be cheaper in the long run to buy a 2M mobile rig. AES has the Yaesu 1500M for $139.00. Can't hardly compete with that, especially if you build a crystal controlled transmitter. If you build VFO style, the cost of the parts in the PLL and the rest of the circuitry, box, etc. will add up and you'll probably only have a Watt or two. Why not start with a mobile that puts out 50 Watts, receives police and weather to boot?

Food for thought.....

Is this in FM mode or CW? If you put it in CW does it dither? Are you
using internal or external modulation, etc. ? Yes, rf is a pain.

BTW, you have to change the modulation scheme going from one to the
other. If you have a loop and a signal falls in the passband of the loop,
it will be extracted by the loop and you will end up with no modulation.

You end up having to modulate the reference or something else to get around the loop tracking.

I wouldn't discount power supply ripple. I have a Motorola S1327B service monitor from same era. It did a lot of squirrly things before I changed the filter caps. The TTL logic is not tolerent of noise. I also found a lot of chips with very tarnished silver pins (gold plated boards with tin plated chip sockets!) replacing those helped a lot. The unit is 25 years old and working better than ever.

3099. MAKE MONEY THE EASY WAY

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-16 01:59:55 UTC
From: cindygmedrano@aol.com
Message-ID: <20021015215955.05821.00002135@mb-mm.aol.com>
Source record: 40661

MAKE MONEY THE EASY WAY

READING THIS COULD CHANGE YOUR LIFE! I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, ‘’Yeah right, this must be a scam’’, but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at # 6, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured : " what have I got to lose expect 6 stamps and $6.00, right ?" Then I invested the measly $6.00. Well GUESS WHAT !! Within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it’s still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it’s still coming in rapidly. It’s certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works. Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.) Follow the simple directions and watch the money come in! It’s easy. It’s legal. And, your investment is only $6.00 (plus postage) IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it’s virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends . PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it’s a service. You are in business of developing Mail8ing lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your

name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office(1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses: #1) Daniel Goldstein, 1485 Biltmore Drive, Atlanta Georgia 30329 #2) Boris Milter 1057 Spalding Club Court, Atlanta Georgia 30338 #3) Gabe Rich, 2444 Sandell Drive, Atlanta Georgia 30338 #4) Justin Allgood 6800 Younger rd. The colony, TX 75056 #5) Greg Pierce 5021 Wheeler cir. The Colony, TX 75056 #6) Jeremy Tovar 139 Westhill San Antonio TX 78201 STEP 2: Now take the #1 name off the lists that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list. STEP 3: Change anything you need t, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 news groups. (There are hundreds of thousands of them)Try Wallstreet Sports, Sandbox Sports, Yahoo auctions, e-mails messages in chat rooms, letters in the mail, signs, anything else that will reach to the public. Be as creative as possible. The more you reach out to, the more $$$. Even make a website. All you need is 200 newsgroups, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 &1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way. NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will reimbursed for their participation as a list Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 (one for each of the first six people listed above) Send it now, add your own name to the list and you’re in business! DIRECTIONS FOR HOW TO POST NEWSGROUPS----------STEP1)You do not need to re-type this entire letter to do your own posting . Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select ‘copy’ from the edit menu. This will copy the entire letter into the computers memory. STEP 2) Open a blank ‘note pad’ file and place your cursor at the top of the blank page. From the ‘edit’ menu select ‘paste’. This will paste a copy of the letter into notepad so that you can add your name to the list. STEP 3) Save your new notepad as text file. If you want to do your posting in different settings, you’ll always have this file to go back to. STEP 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, messages boards, chat sites, discussions.) STEP 5) Visit these massage boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the subject, this will be the header that everyone sees as they scroll through the list of postings in a

particular group, click the post message button. You’re done with your first one! Congratulations..... THAT’S IT! All you have to do is jump to different news groups and post away, after you hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That’s it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O. Box due to the large amount. THIS IS NOT AN AUCTION BUT A OPPORTUNITY! Thanks for your time and you can bid if you want more money making opportunities like this one!!! I GUARANTEE THIS WILL WORK. IF IT DOESN’T WORK, WRITE TO THE BOTTOM PERSON ON THE LIST. HE WILL TRY TO GET YOU YOUR $6.00 BACK. YOU WILL GET AT LEAST $1.00 BACK IF IT DOESN’T WORK (FROM THE PERSON ON THE BOTTOM OF THE LIST) 30 DAY MONEY BACK GUARANTEE!!! (NOTE: THIS IS PERFECTLY LEGAL. I I WILL TRY AND GET $6.00 BACK, YOU WILL AT LEAST GET $1.00 BACK. SEND SASE TO BOTTOM ADDRESS DEMANDING FOR REFUND, WILL NEED PROF THOUGH.)

3100. MAKE MONEY THE EASY WAY

MAKE MONEY THE EASY WAY

READING THIS COULD CHANGE YOUR LIFE! I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, ‘’Yeah right, this must be a scam’’, but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at # 6, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured : " what have I got to lose expect 6 stamps and $6.00, right ?" Then I invested the measly $6.00. Well GUESS WHAT !! Within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it’s still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it’s still coming in rapidly. It’s certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works. Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.) Follow the simple directions and watch the money come in! It’s easy. It’s legal. And, your investment is only $6.00 (plus postage) IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it’s virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends . PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it’s a service. You are in business of developing Mail8ing lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your

name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office(1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses: #1) Daniel Goldstein, 1485 Biltmore Drive, Atlanta Georgia 30329 #2) Boris Milter 1057 Spalding Club Court, Atlanta Georgia 30338 #3) Gabe Rich, 2444 Sandell Drive, Atlanta Georgia 30338 #4) Justin Allgood 6800 Younger rd. The colony, TX 75056 #5) Greg Pierce 5021 Wheeler cir. The Colony, TX 75056 #6) Jeremy Tovar 139 Westhill San Antonio TX 78201 STEP 2: Now take the #1 name off the lists that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list. STEP 3: Change anything you need t, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 news groups. (There are hundreds of thousands of them)Try Wallstreet Sports, Sandbox Sports, Yahoo auctions, e-mails messages in chat rooms, letters in the mail, signs, anything else that will reach to the public. Be as creative as possible. The more you reach out to, the more $$$. Even make a website. All you need is 200 newsgroups, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 &1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way. NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will reimbursed for their participation as a list Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 (one for each of the first six people listed above) Send it now, add your own name to the list and you’re in business! DIRECTIONS FOR HOW TO POST NEWSGROUPS----------STEP1)You do not need to re-type this entire letter to do your own posting . Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select ‘copy’ from the edit menu. This will copy the entire letter into the computers memory. STEP 2) Open a blank ‘note pad’ file and place your cursor at the top of the blank page. From the ‘edit’ menu select ‘paste’. This will paste a copy of the letter into notepad so that you can add your name to the list. STEP 3) Save your new notepad as text file. If you want to do your posting in different settings, you’ll always have this file to go back to. STEP 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, messages boards, chat sites, discussions.) STEP 5) Visit these massage boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the subject, this will be the header that everyone sees as they scroll through the list of postings in a

particular group, click the post message button. You're done with your first one! Congratulations..... THAT'S IT! Yes, I have begun to look around for one of these 140/141T's. My only
concern here would be how it would hold up, especially being used. Also,
how easy/difficult is it to service yourself if the need arose?

Today we have the terrorists. I had family only two blocks from the big one
in Bali last week.

When I was of college age we had the threat of someone pushing a putton and
blowing it all away. If you've watched the news lately you know just how
close we were to putting out the lights.

The world today isn't any worse than when I was a kid, or teenager, or in my
20s.

The problems may come under a different name, but I actually think things
are a bit better now over all.

Quit worrin' and get back to work.

This is in plain CW. The reason I suspect the FM circuit is that even when FM is switched off, the FM circuit is still active and the possibility of modulation by contact noise is still there.

I also note Joe's point about the power supply. It's not normal ripple, but all these instruments are now of an age where electrolytic capacitors become suspect, so that's something to look at too.

I was really only wondering whether this dither was a known common fault, or whether I have to go into the full trouble-shooting routine. Looks like the latter... but thank you, everyone.

Ameco PT-2 preamplifer: Covers 160 to 6 meters, automatic Tx/Rx relay
passes up to 200 watts. Receive bulb is burnt out, but otherwise it
works great! Would make a fine front-end for a shortwave receiver or
homebrew ham rig. Manual can be found here: www://6mt.com/e1.zip
$60 shipped in ConUS

OneAC CL1101 line conditioner: Rated 1.0 Amp output at 120VAC, single
socket. This is a special isolation transformer + capacitor inside a
case that's flanged for mounting anywhere. Better than a surge
protector or line filter against spikes, surges and other line noise.
$40 shipped in ConUS.

Book: "RF Microelectronics" by Behzad Razavi, Prentice Hall, 1998.
Book is like new, just some wear on the cover from shelf-shuffling
(it's an extra copy from the shop). Check it out at Amazon:
http://www.amazon.com/exec/obidos/ASIN/0138875715/ref=ase_absolutsearch05/103-3859525-6143
843
Amazon's price: $93.00. My price: $30 shipped in ConUS.

Joe is right. I didn't think of that because I thought that we were
talking B model. When you go back in history to the early days of UHF
radio on the ham bands, hams used to use AM modulated oscillators for
short range communication. What they got instead was a very wide signal
due to both AM and unintentional FM on the xmtr. If anyone is interested
in the why, I could send them an email or they can look up the reactance
modulator explanation in one of the old Orr Radio Handbooks. What is
important is that modulation of the B+ in an oscillator or even its buffer
is ungood. No matter how nice the equipment looks, if the electrolytics
are more than 15 to 20 years old, they are probably close to useless as
filter caps. Change as many as you are able without a manual and then
change them all if you get one. The other caps that HP used were
extremely stable mica's, etc. You won't find any paper caps in HP
equipment, I would bet. Watch, someone will send my a bill of material
for a HP200 oscillator with paper caps on it. :-)

Cavity oscillators are clean and fairly stable. There should be no FM
associated with them in CW mode. If there is, then Joe's point is the
best one that I've seen suggested. If you can puzzle out where the
oscillator section is, replace every electrolytic you can find. If you
find some tantalum's, then replace them too, but only if the electrolytic
change doesn't do the trick.

I didn't ask yet, but did you put your oscope on AC couple and look at
what ripple you do have on the various supplies? I don't remember the
architechure of the gen so ripple elsewhere could also contribute to your
dither.

Source record: 40675

Hi all,

Harry's Homebrew Homepages - http://w1.859.telia.com/~u85920178/

We have had a very nice and long summer here in Sweden, so work on the page was a bit slow. There are, however, some new projects, including:

TRANSMITTER - AM CW RC TX
Basically an AM transmitter that delivers 200mW. Usefull for CW, AM and radio-control of models. Crystal controlled but will operate on crystal harmonics. Article gives coil winding from 1MHz to 40MHz.

TRANSMITTER - V7 and V7b
A fre-running 400mW VHF FM transmitter that can be modified for 50MHz, 70MHz and 144MHz NBFM. Leave it as it is and ic covers 88MHz - 108MHz WBFM. the V7b included pre-emphasis and even an on-board prescaler for adding a simple CMOS only synthesiser.

DOWNLOAD - PCB and foil patters for above.

I was selling kits for the V5 (VHF WBFM 10mW) but these were handed over to Lycom Co in the UK. Sales via Lycom have slowed down so I am offering them again. Just building up stocks at the moment.

New kit added over summer - All CMOS Frequency synthesiser. All board mounted components, including crystal resonator frequency standard. Synthesises 50KHz to 800KHz in 1KHz steps, extended to 3.5MHz. Can be extended to 15MHz with external VCO. With external VCO/Prescaler - light?

Best regards fromHarry - SM0VPO

I don't think the problem is due to ripple as such, because the
dithering is pseudo-random.

>I didn't ask yet, but did you put your oscope on AC couple and look at

Not yet, but that will be the first thing when I open it up.

> I don't remember the architechure of the gen so ripple elsewhere could
>also contribute to your dither.
>
It's a 256-512MHz cavity oscillator with cascaded divide-by-2s. Come to
think, I need to check the fundamental against a 432MHz receiver to see
whether the ripple is in the oscillator or comes in further down the
divider chain.

Another thing - where is it? Don't put it on top of a video display or near an electric motor. You can imagine the problems I have Ian. Just look at the web page (213.152.32.180/Spectra/index.html) for an example of what an intense magnetic field can do for you.

I think the sidebands at 50Hz on strong signals are caused by direct modulation of the VCO.

3119. Re: Homegrown Li-Ion battery pack for FT-50

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-16 10:24:39 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uqqfj19pdlnq1d@corp.supernews.com>
Source record: 40676

I took apart a couple of laptop battery packs and salvaged some similar Li-ion cells. The MAHA 777+ seems to charge them according to manufacturers' specs for similar cells. So I don't see anything wrong with doing what you're planning, except for two things. One is to make sure that you don't exceed the manufacturer's maximum discharge rate. For the ones I've investigated, this is C, in your case 1.8 A. Don't use the cells if your rig draws more than this on transmit. The other precaution is that the cells can be permanently damaged if allowed to discharge below 3.0 volts per cell. So don't use them unless you have a circuit that disconnects the battery when the cell voltage drops to this value.

Ni-MH cells are generally a better choice for this type of service because of the Li-ion cells' limitations. In applications like a laptop, you'll see a circuit board inside the battery case which takes care of the charge and discharge restrictions. But if you were going to scrap the cells anyway and already have the charger, you might as well get some use out of them.

You can get more information about the care and feeding of Li-ion cells on the Panasonic web site.

The 141's ect are reliable and eminently servicable. They are full of
metal sheeting, PCB's, wires, transistors, diodes, resistors, cap's
and L's.
The service manuals are superb.

Note though, that the initial mixer frequencies are -high- and would
need capable test gear to fault find in these areas.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday October 20th 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

I often have this complaint- but in this case the item was both- FS and FA- and
in fact the auction ended by FS

3123. Yeasu Multi-CAT Circuit pse?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-16 13:35:58 UTC
From: Ken Page <vk4akp@yahoo.com>
Message-ID: <3dad6764@dnews.tpgi.com.au>
Source record: 40684

Hi, I'm looking for the circuit for the Multi-CAT interface to suit the Yaesu radios. I have seen reference to it on the net, but can't find any info.

I believe it uses two rs232 lines to select between four different radio's but using only one com port.

I wish to run a Yaesu FT-890AT, FT-757GX & FT-212RH off the one CAT interface.

I'm also looking for info on how to make the multi-drop Kiss interface to run 4 TNC's off the one com port. (2x PK232MBX's & 2x PK88's).

Any help appreciated!

Regards,
Ken. VK4AKP.

Talking of service manuals do HP sell them for anything, I have an 8591E with a power supply fault and I can't fix the thing. Does anyone know how much they cost or how to get them.

And on Ebay, when the seller uses the "Buy it now" option with a
instant selling price shown, it is both for sale immediately and for
auction if no one decides to "buy it not" at that price

Hello. I have a small touchlamp, with 3 brightness settings. I've heard from other newgroups that touchlamps radiate an EMF/EMI field which can interfere with radio equipment.

I often store electronic stuff mere inches from the lamp, like my cellphone, Zip disks, MP3 player, etc. Can any equipment like this, turned on or off, be damaged (even slightly) by remaining near a touch-lamp for long periods of time?

Thanks!

I don't think it is powerful enough to damage electronic equipment,
but it can easily interfere with its normal functioning like any RFI.

It could interfere with radio reception, and potentially erase or
scramble magnetic memory, like a hard disk, floppy disk, Zip, backup
tape.

The distance is important for any electromagnetic effect, once your
stuff is more than a foot away the effect will be unnoticable. RFI can
carry further.

Happy trails,

I don't particularly care, though I think it's silly when someone simply
posts a link to an auction, rather than put some detail into the message.
And it is silly when someone doesn't bother mentioning in the header
that they are selling something in some way.

But the issue of auction versus forsale just seems to be a way of
ignoring a bigger issue, which is ads in discussion newsgroups.
By arguing over the ebay ads, we ignore the fact that these newsgroups
were set up for discussion. Once we've let ads in, one can hardly
discriminate against auction ads, or treat them like they are somehow
something much slimier than simple forsale ads. Both are relatively rude,
and usually come from people who are more interested in selling things
than in the actual newsgroup.

>I've used the 564 for FSK demodulation with a 50MHZ carrier and it worked
>well. Should be OK for your app - hope the D version is suitable.

Well, I have 3 NE564's laying around somewhere, I'll dig them out and test them.

but ....

It was the low max MHz operating point and availability reasons why I decided not to use the NE564 (what with the 13MHz BW requirement, well, at least for a good enough video quality), but I've since found out that the NE568 is just as non obtainable anyway :(... was given a uk source by someone else but they too no longer have them, even though their web site shows they do/can get them.

Looking like I'll have to resort to using the 480MHz devices and laying out a discrete vco for the freq so I'll prolly do that, although a vco at around 480 is 'not' that hard to get going, it's ease/simplicity/cost of construction I'm looking for atm, so a ready made SMT vco I'll prolly go for like the microwave devices types etc.

Clive.

3132. SAA1057 / TSA5511 PLL's

> wondered if it is a Known Problem.

Well, it does have some phase noise. Any way you can characterize the
noise you see spectrally? Does it meet spec? (I can supply specs if
needed.) I'd go looking for things I can correlate it to; there are
lots of tricks you can play to localize where it's happening. How is
the phase noise amplitude versus band, for example? -- That is, does
the problem show up on the 256-512MHz range and on lower ranges in
proportion, or is it stronger than it should be on the lower ranges
only? Mechanically-tuned cavities can develop mechanical instability
as they age, so that's a possibility. I guess in the "A" version you
don't have phase locking...

Cheers,
Tom

> years. Someone correct me if I'm wrong, but the HP8640B is frequency
> locked and not phase locked.

OK, please stand corrected. It's most certainly phase locked. The
reason you have to re-tune if you lock before it's warmed up is that
the VCO part is accomplished with a lightly-coupled varicap diode in
the oscillator cavity that has a very limited range of frequency
adjustment. When the cavity drifts off too far, there's no way the
varicap can keep it locked (phase or frequency). But locked, it
really is a phase lock.

Cheers,
Tom

Actually, I've met up with way too many individual micas that have
nasty small instabilities to think of them as "extremely stable."
It's been rather a long time since we've used any of them around here,
though they were fairly common in the 8640 era.

Cheers,
Tom

>for a HP200 oscillator with paper caps on it. :-)

In general, I believe HP used parts which they thought were the best quality available. While most of my older HP gear still has electrolytics in them which are original, some have failed. And yes, the 200CD has 4 paper caps in it. While these are almost always bad by now, I have one unit at work where they are all still fine.

OTOH, one of the mica caps in my first 200CD was leaky when I got it. By that time it was probably 35 years old, however. The paper caps in that unit were all bad, but the electrolytics are all still bad. This was a late 50s unit.

I have quite a few HP items from the 70s where the electrolytics are still fine, but I just fixed a 70s DMM last weekend where the + & - 22V PS rails were both completely dead. Boy, did THAT ever make a difference!

What temp do you guys set a temperature-controlled soldering station
to for typical printed circuit, etc, soldering with typical solder?

I picked up one of these at a hamfest this past weekend. I get a
readout of tip temp.

I have never used one before, and need some guidance. It is easy to
find what temp my solder melts at, but how much higher than that works
best for typical use?

TIA

Jerry From URL:
http://www.epemag.wimborne.co.uk/solderfaq.htm#Temp

Temperature
Another step to successful soldering is to ensure that the temperature of all the parts is raised to roughly the same level before applying solder. Imagine, for instance, trying to solder a resistor into place on a printed circuit board: it's far better to heat both the copper p.c.b. and the resistor lead at the same time before applying solder, so that the solder will flow much more readily over the joint. Heating one part but not the other is far less satisfactory joint, so strive to ensure that the iron is in contact with all the components first, before touching the solder to it. The melting point of most solder is in the region of 188�C (370�F) and the iron tip temperature is typically 330-350�C (626�-662�F).

Has any one here, or can direct me to resources, to modify an 800 Mhz AMPS (old analog modile set) cellular phone into a half duplex/simplex 900 Mhz transciever? I figure it won't be too hard, other than to make sure it is operation properly in band. I'd be dumping the CPU electronics, and removing the cell band filters, or modifying them for 902-928 Mhz use. The RX LO is usually around 936 Mhz, so it won't be too hard to rework. I can use a micro to program the PLLs.

The temp should be enough to melt the solder on the joint you are wanting soldered, this varies much, depends on the size & type of metal being soldered.
For most soldering my station runs 600-800 dregrees F.

Jerry,

Generally 700°F works for average tips and general purpose soldering
chores. Lower it to 600°-650° for small tips and fine pitch soldering
and raise it to 800° for your heavy ground lugs and things like that.

Just remember, the lower your tip temperature, the longer your tips
will last. So if you DO need to go to 800°, don't let it sit there in
the holder for hours on end without lowering the temp back down.

Cheers,
Mike

I have seen references to modifying old CMOS keyers to work with the newer rigs, but can't find any schematics on the web. I have an old Trac TE122 that I would like to get to work with my Kenwood 450. Can anyone help me out or point me in the right direction? Thanks.

> soldered.

If the tip is really temperature controlled you shouldn't have to change the temperature setting depending upon the size of the joint (within reason). If the joint absorbs more heat and the tip begins to cool, the controller should increase the power to the tip to keep it at the set temperature.

Just a follow-up. As a result of Dick's enquiry I dug out the
paperwork i have on protection modules. There is data from Nexcon
Technology (unfortunately not fo release to unauthorised persons) and
Seiko. The Seiko S8232 2-cell protection module has its overvoltage
detection threshold set at 4.20V+/-25mV through 4.35V+/-25mV.

If anyone is interested, I could possibly email an Excel chart showing
the charge cycle V/I. This might better illustrate how easily even a
low a current source will get these cells into the overvoltage region.
Without an overvolt protection module, you are then in tiger country.

Roy, I have read your posts with a deal of interest and respect for
quite a period, so I was interested in your comments here.

Unfortunately I am not familiar with the MAHA charger so I can't
comment. However, I will add that I have seen a number of
commercially available chargers (usually Asian origin) labelled
"universal" and claiming to charge NiCd/NiMH and Li-Ion. Our
examination of these shows they do NOT in general employ a CLCV
regime. According to manufacturers' recommendations we have at hand,
a tightly limited voltage is necessary, and I would add especially so
where no protection module is fitted as a safety measure.

Your other comments are endorsed.

Good idea but UIAVMM it won't work. All the PM's I've seen are
specific to the cell count, and cannot be configured to work with a
series string of less cells.

Jim:

Are you sure you aren't thinking about mods to allow CMOS keyers to work with older rigs, like the cathode keyed vacuum tube transmitters? I would think that a CMOS keyer probably has the ability to key any radio as modern as a TS-450 without mods.

Hi Jerry,
I set my soldering iron to 300-330ï¿½C (570-630ï¿½F) for common PCB and thin wire soldering. I use a Sn60Pb solder wire 1,0 mm dia. For thick wires and big joints I use a higher-power unregulated soldering iron.

The MAHA MH-C777 plus has different, switch selected, charging regimens for NiCd/NiMH and Li-ion cells. I see they're now offering an MH-C777 plus II model. There's some information about this newer model at http://www.mahaenergy.com. I haven't done any test of my MH-C777 plus except to compare the state of charge (determined by a timed constant current discharge) of MAHA-charged Li-ion cells with ones manually charged according to the Panasonic recommendations. There wasn't any appreciable difference in the capacity obtained with the two charging methods, so within the bounds of this very limited test, the MAHA seemed to do what it claimed.

I was surprised to find that the Li-ion cells I have don't have that much of an edge over NiMH cells with regard to energy per unit weight. But the Li-ion cells I have are quite a few years old, salvaged from non-working packs from an old laptop computer, and I was comparing them to modern NiMH cells. Considering the extra care the Li-ion cells require, the relatively small weight advantage isn't worth the bother to me. I imagine that more modern Li-ion cells would show more of an advantage, but I don't (yet) have any source of cheap or free ones. Guess I'll have to wait until the batteries of my current laptop go flaky.

========
The MAHA C777PLUS charger/analyser is in sofar universal that one has to
manually select whether the battery (pack) is Ni or Li.
As per the instuction manual :
NiCAD and NiMH batteries are supported from 1.2 to 14.4 V Rapid charge
current 800 mA plus/minus 50mA
Li-ion batteries are supported from 3.6 to 14.4 V Rapid charge current
400 mA max.

Trickle charge current 70 mA

Voltage accuracy plus/minus 0.3 V

Detection : Negative Delta V - Zero Delta V - Max temperature

This keyer does not do 'direct' keying. If I put an ohm meter across the keying leads, I get no deflection. It's a pretty old keyer and I have no documentation for it, so I can only assume it's a negative line keyer intended for use in grid block keyed transmitters. I would like to see if I can change it for 'direct' keying. I've seen references to using reed relays and such and I am looking to see if anyone has more specific details on how to do it, or any other 'better' way. Thanks.

Thanks to the replies. The consensus was that the keyer should work. Well, Mike Willis suggested I check the polarity of the output leads with an Ohm meter and I did get a reading. So, all I did was reverse the output leads and now it works fine. No mods necessary! Thanks to Mike Willis!

Interesting observation. I modelled our commercial/industrial Li-Ion
charger design around the 18650 cells. They are 42g and variously
1700mAh to 1800mAh for a 3.0V end-point. I just weighed four 1800mAh
NiMH cells and got 104g, albeit on the kitchen scales, so working on
+/- 10% thats 24-28g each. For the Li-Ion's we use 3.6 as the mean
voltage on discharge vs say 1.2 for the NiMH. So that gives 3 times
the grunt for about 60% more weight, or nearly twice the
energy/weight. If your comparison isn't that favourable then it could
be the condition of your Li-Ions that lets them down.

There are certainly areas where Ni-anythings will shine over Li-Ion.
One is charging rate. Using the CLCV regime, we wwere getting about
98% return in three hours, but only 50 minutes or so was in current
limit. SO even if we cranked the CL up by a factor of two, the
reduction in cycle length would only be 25 minutes MAX - hardly worth
fussing over. In a design in hand for some large-ish NiMH packs (20
cells of 13Ah) we are considering charging at 4C and using dT/dt
termination only. After transition to trickle, this will give us an
estimated 90% plus recovery inside 30 minutes. If recovery speed is

any sort of issue, Li-Ion aren't in the photo frame at the finish.

The other aspect to use of Li-Ion in the O/P's context is discharge current capability of the L-I's. Apart from any PM intervention, I have personally experienced cells which suffered a transient short by a wandering meter lead, and were never able to deliver anything useful thereafter - almost as if the cell itself contained a fusible link with a high R across it.

In case you are interested, our capacity and coulomb efficiency measurement was done with a constant load R and numerical integration of V/I samples taken at 1 minute intervals with a mean load current of ~0.5C. Samples were taken with an HP34970 which is quite an accurate basis for such calculations.

Thanks for the heads-up on the specs. I only hope that the voltage
accuracy is better than that on (for example) a single Li-Ion. 3.9V
won't give you a great charge restoration, while 4.5V would have me
move out of the room real fast.

==========
To interface the keyer with a valve transmitter you could use an
opto-coupler followed by a suitable high(er) voltage transistor if
necessary . A good HV transistor is the SD869 originally used for video
sweep and good for 1500 V.
In principle I would always use an opto-coupler to interface a keyer with
any transmitter.

On a different but related subject , years ago I have seen a circuit for a
VFO employing a high-speed opto-coupler to avoid any possible variable
loading .
In general , opto-couplers can prevent a lot of potential interfacing hassle
; I love them .

3165. Building a variable condenser?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-18 18:46:22 UTC
From: la8ak.xnd@online.no
Message-ID: <3db02277.170352299@news.online.no>

Cross-posted to: rec.radio.amateur.homebrew,se.hobby.amatorradio

Capacitors for ATU are difficult to find nowadays, and a friend are travelling to Taiwan with one of the purpose of finding variable capcitors for ATU projects.

Have seen ATU's for sale in Germany with tuning capacitors which looks like 'home-made', but quite good work. Wonder if somebody has experience in making his own variable capcitorsm and what is possible maximum capacity?

I am particularly interested if it is possible to make a 5000pF 2000V or larger capacitor for 136kHz ATU, dimensions for 136kHz could be 100 times larger than 14MHz for similar performance. Suggest mica as dielectricum?

I have made homemade caps in the past but nothing approaching what you want,
I thought most lowfer equipment was very low power, are you sure you need
that 2000v spec?

Do you need the full 0-5000 swing for the variable cap? Or could you break
it up into a fixed cap and a smaller variable cap?

If creating a rotating varible is too difficult for you, you might make one
with a sliding adjustment, that is how my first variable was designed, I
just used a sliding track to mesh the rectangular plates together instead of
rotating them together.

Whatever you do, make sure you keep everything insulated, both from the case
and from the knob, ceramic standoffs seem to be in shorter supply around
here than variable caps.
thanks, John.

You can get some pretty good sized air variable caps on ebay and elsewhere, and then you can triple their size and voltage rating by immersing them in mineral oil. Build a tank that will hold the cap and the oil, then add an insulated shaft extention to bring the shaft out from the top. It may not be pretty, but it works very well.

=======
A variable capacitor of 5000 pf - 2000 V can perhaps be best made by a low - 1000 pF variable vacuum cap with additional 4 switched fixed 1000 pF HV caps . using a HV ceramic switch , adding/reducing 1000 pF to the system each step

The 1000 pF - 3000 V (Jennings) variable vacuum cap can be found in Collins aircraft ATUs which a few years ago were sold by surplus trader J. Birkett - Lincoln in the UK . He still might have a few . He regularly advertises in the RSGB's magazine RADCOM.

The HV fixed caps can often be found in surplus 2 MHz marine equipment or on fleamarkets in continental Europe ,nowadays 'teeming ' with HV components of Russian origin. In this respect personal contacts with fellow radio amateurs in (the eastern part of) Germany , Poland or the Baltic states might be useful.

Alternatively a 500 pF HV variable air cap. with added switched 500 -1000 - 1000 - 1000 - 1000 pF fixed HV caps.

You can even use a lower capacity HV variable air cap often available ex WW2 equipment (eg BC-602 tuner) but then you need more fixed caps with a smaller capacity and hence a more position 'adding' switch to enable a smooth step wise increase/decrease of capacity.

I've read articles (in QST or other ham-related magazines) which made
variable capacitors out of short lengths of concentric tubing separated
by thin plastic; just slide the tubing in/out to change capacitance.
However, I don't recall capacitance values.

I have just bought the techniks "press n peel"kit for making PCB'S my question concerns the directions ,the first step, where you photocopy the circuit image onto the dull side of the emulsion. Not being used to photocopiers,which way faces up as it is loaded into photocopier the shiny side or the dull side,I've only got a few sheets and don't want to waste them,.
Mark.

I know the problem from trying to do double-sided copying. Simple
solution - take a sheet of plain paper and write "this side up" on the
side that is up (logical, but I figured I should say so). Then shove
that through the copier, and the result will solve your dilemma.

Best way is to take a piece of paper. Make a mark on it. put face down in the paper tray. make a copy and see if the mark is up or down in the output tray. then you know which way to put your sheet.

This works well. Remember that different models will vary, so check on
the one you are actually using. For a printer or copier you use
frequently, you might want to put a label on the paper tray when you
figure it out.

Also useful for double sided copies, letterhead, label stock, special
stock, and so on.

Most paper trays manufactured in the past decade have an icon indicating
print side. If it prints on the side facing down, it shows a corner folded
with squiggly lines of print showing on the folded portion.

Although if they actually were visible, this wouldn't be a problem.
They are often a raised molding in the plastic, in exactly the same
color.

Fax machines have similar labeling, and I have seen faxes of the back
side (blank) of something more than once.

700F is a very good choice.

Higher will oxidize the tip quickly while lower may work too slowly
for some jobs. If you have a lot of work to do with it you can
experiment and see if you can get by with lower, but I wouldn't expect
anything below 650F to be satisfactory with normal solder and normal
parts.

Why not mark a sheet of photocopy paper with a message like "this
side" copy a document and see if your scribble gets overwritten ;-)
either way you will know what way to fit your 'Press and peel" stuff

Sounds like a good idea, and the capacitors should be relatively easy
to build too (save for their possibly awkward dimensions. The capacitance
should be easy to calculate from surface area, spacing, and dielectric
material.
For higher frequencies (or rather lower capacitances) I think a project
in the Handbook used two plates at variable distance from each other.
Building a 5000 pF unit like that seems quite impractical, though.
Good luck,
Hans-Christian W6/SM6TLH

I need to measure a 20mV 1440 MHz oscillator signal. Is it possible to do so with a homebrew RF probe that can measure into this UHF range? If so, can anyone recommend a suitable design? Any help greatly appreciated.

How about fixed caps in binary with relay switching? 2500 pF 1200 pF
600 pF, etc. Building fixed caps is pretty easy and at 136 KHz, relay
switching isn't hard either with very inexpensive relays.

Eight relays = 256 steps = about 20 pF/step.

If that gives steps that are too coarse, then use say 5 relays = 32
steps = 156 pF/step and a 200 pF continuous variable as a vernier.

I have to ask why such high voltage ? Isn't 136 khz a low power (under 10 watts or so) frequency or is it that you can run much more in your country ?
I have to admitt that I know very little about that frequency.

I worked for Motorola in the Comm Sector for 7 years, and I never saw any model number for anything in that product line that looked even remotely like '3c23.' Honestly, it sounds like the part number for a tube.

Do you have a better description? What is this mysterious "unit" supposed to be?

Keep the peace(es).

What is the layout of the circuit. Is it a Colpitts with the
drain/collector driving a common base/gate buffer or what? Also, where in
the circuit did you want to probe? At these freq's a small C added to
the circuit from the probe can pull the oscillator off freq or even kill
the oscillation. If you can identify a low impedance point in the circuit
then you run a better chance of not causing any problems. For instance in
the above described circuit layout or typography, the drain or collector
of the oscillator could be probed with minimal effect because the node is
a low impedance. As far as the probe itself is concerned look at the
Agilent web pages for zero bias Schottky detectors. There is also a ic
called the LTC1957 which might do what you want, but the input may require
a buffer with very little input cap and basically no R to ground. We're
talking high impedance if you need absolute readings.

Hope this helps.

Any logo's on the part? Are they SOT 23's ? I searched Questlink and found no match for the PH146, but I didn't try the others or try to go through the partial of PH. The PHXX number may just be a marking if the device is in SOT type of case. If so, searches are hit and miss at best.

I worked for Moto Comm Sector for 22 years. What type of radio are we talking?
Portable, fixed, mobile, or satelite? Does it look military or HT type?
The 3C23 is part of what number? Moto made base units, terminals,
mobiles, portables, PT's, portable repeaters, etc. Give me a description
as best you can and I can probably steer you in the right direction. For
example, if it is carried and has a handle and looks like a lunch box then
it could be a PT500 or the like. If it's full of fire bottles, weighs 50
lbs, draws 20 amps in xmt and puts out 20 watts on 2mtrs, then it could be
a 43GGV mobile. I'm not trying to give you a hard time, but a little
description goes a long way when it comes to Motorola radios.

>watts or so) frequency or is it that you can run much more in your country ?
>I have to admitt that I know very little about that frequency.

The 136 kHz started in Europe in 1997 (I think by CEPT) recommending
to the national administrations that the band could be created and
that the _radiated_ power (ERP) should be below 1 W.

Some countries copied this directly to their amateur radio rules,
while other converted this to a transmitter power rating assuming some
specific antenna efficiency. For instance in Finland, the maximum
transmitter output at that band is 100 W, which assumes an antenna
efficiency of 1 % which corresponds to an antenna gain of -20 dB (yes
that is minus 20 dB).

However, an antenna system efficiency of 1 % is very optimistic at 136
kHz for any typical antenna system built by hams, with towers
typically up to 30 m. The 1 % efficiency would be typical for maritime
and aeronautical beacons in the 300-400 kHz range with 50-60 m towers
according to field strength measurements on the ground and by in
flight measurements.

For a typical ham installation at 136 kHz a representative antenna
system efficiency is closer to 0.1 % (-30 dB gain) than 1 % (-20 dB
gain), thus, up to 1 kW is used in some countries to drive small
antennas, producing nearly 1 W of radiated power.

With typical antenna highs of about 1/100 wavelength, the radiation
resistance is well below 1 ohm. It is also capacitive, so a large
loading coil is required to resonate the antenna system.

Now the question is, does it make sense to build a transmitter with 50
ohm output impedance and use traditional pi or T antenna tuner to
transfer the impedance to something close to 1 ohm. Such high
impedance ratio will require quite different capacitor or inductor
values and can generate quite large voltages or currents in the ATU
components.

One other approach would be to use some wide band audio amplifier with
low output impedance and use an ordinary (ferrite) transformer to drop
the impedance level even further and then use multiple taps in the
loading coil to resonate the antenna.

A constantly variable inductance could be built by inserting some ferrite material into a large inductor with air core, or use two inductors, one fixed and the other that can be moved and/or rotated relative to the fixed inductor. With both inductors in line the inductance is about twice the sum of the inductances (since inductance is proportional to the number of turns squared). With the movable inductor perpendicular to the fixed inductor, the inductances are independent, thus the total impedance is equal to the sum of the individual inductances, with moveable inductor in the opposite direction, the inductances nearly cancel.

This variable inductance could be located at the base of the antenna and then it could be remotely tunable.

By rethinking the transmitter and antenna matching system, you can get rid of the need for huge variable capacitors with high voltage ratings.

20 mV would be about -20 dBm into 50 ohms and many simple passive probes have usable sensitivities to 1 mW or perhaps 0.3 mW at 1300 MHz.

If you are only interested in detecting the signal for tuning purposes, a simple stripline amplifier consisting of one or two MAR-x or MAV-11 MMIC could be inserted in front of any passive detector to bring the signal level up to a few mW.

If you really need to measure the signal level, then you have to calibrate the system with a known signal level (signal generator etc.). Fixed -10 dB and -20 dB attenuators built into BNC or SMA barrel connectors are useful to drop the signal level sufficiently, so that the MAR/MAV does not saturate. The gain of these MMICs vary with collector current, temperature and frequency, so for accurate measurements, the calibration needs to be done before each measurement.

Very interesting.

But while the radiation resistance is well below one ohm, is it really possible to get the ground and inductor losses low enough that you'll actually have one ohm at the feedpoint? Even with a fairly elaborate ground system you'd have two or three ohms of ground loss resistance, and depending on the tower diameter and whether you have a top hat, you'll need somewhere around 1000 - 5000 ohms of reactance for loading or matching. That will add anywhere from a few to 20 or so ohms of resistance, depending on the Q you can achieve. My guess is that all but the best installations will have a feedpoint resistance of at least 20 ohms or so, making matching to 50 ohms relatively simple.

The audio amplifier approach might still be a viable way to go, provided that it doesn't mind a load that's about 8 ohms only over a very narrow frequency range. It might be necessary to also hook its output to an 8 ohm resistor through a lowpass filter to keep it stable. But I'm sure the lowfers have been through all this, and they certainly know a great deal more about what does and doesn't work than I do.

From what I observe at the two Radio Shacks in my area, they are cutting back dramatically on small parts and 1N34's are just part of the cutback -- nothing to do with 9-11.

I have trying to build a couple of small items recently and have made four trips to these two RS stores -- came back empty-handed each time. People at both stores told me they are not longer carrying most of the small parts. One store has even installed a new cabinet that holds the connectors that were previously hanging on the displays.

I image it may be expensive, but you may want to try a 1N62 or other type
diode. Does your application really need the 1N34? Are you willing to
design around another part? If it's Vf you're after, maybe a schottky
part might do.

The challenge there, of course, is that you either need a really strange switch, or some sort of logic. Pretty easy to do with a PIC or something similar, but that seems to spook a lot of folks.

I would appreciate preferences for some PCB design software suitable for
a newbie.

I found this list:

http://www.olimex.com/pcb/dtools.html

I had a quick read on the Eagle site and it looks quite comprehensive.

A package with benefits for RF designs would be an advantage.

Feedback appreciated.

That's the LDG AT-11 automatic antenna tuner. It uses several relays to
switch in fixed caps. 68HC11 controlled.
Works great btw.

Thanks for the explination. As I said I knew very little about the rules.
Maybe that 1 watt erp is where I got the low power from. I understand how
it takes up to or maybe even more than a KW if the antenna is not very
efficent.
I did a 'google search' o the band and it is interisting.

You can buy a binary-decoded rotary switch with 4 lines. You could use
two of those if you want a simple, no PIC design.

One switch for coarse and for fine. Both marked 1...16. (Or, 0..15 if
you are a computer type!)

As far as dealing with the 2kv, granted if you buy those relays
off-the-shelf it will be expensive.

But, you could modify a standard relay for increased voltage standoff
without huge difficulty if you are mechanically inclined.

Could also look for some junked industrial 480 volt contactors. Those
have a lot of over-voltage designed into them. Stray C and L
presumably wouldn't be as much of an issue at 136 KHz. Wouldn't want
to switch RF with a contactor at 28 MHz, but suspect it could be made
to work at 136 KHz.

If it isn't to be remote controlled, you could use something as simple
as a knife switch. Those are cheap and can be found at the hardware
store and will take many KV. Might be a pain in the backside to tune,
or at least to keep track of which switch does which C, but presumably
it is a set-once or seldom-adjust situation, so the inconvenience may
be acceptable.

They only want to sell big ticket items with a large profit margin, TVs,
stereos, computers, cell phones and the like. The original concept of a
retail electronics parts store is no longer viable according to the bean
counters.

Then they may be in trouble, because small retailers for big ticket
items located in high rent spaces aren't viable as long as Best Buy
and the like are around. They can't compete on prices for tv's and
stereos with bigger stores, and they can't compete on prices for
common cables and connectors with Wal-mart. Their only hope is to keep
a wider set of technological goodies.

Yes, you are right, the grounding losses can be quite large, unless
you live at the shoreline of the Dead Sea :-). The Q might be a few
hundred with Litz wire, so the feed point impedance is over 10 ohms in
nearly all cases and thus, not too difficult to match to 50 ohms.

But anyway, I don't think that the original idea of using huge
variable capacitors to achieve this matching would be very practical
at these frequencies, while other alternative methods (tapped loading
coils and variometers) are available.

If you do not like the PIC or programming, just use two 4 bit CMOS
Up/Down counters and a multichannel darlington buffer to drive the
relays. Some LEDs for feedback could be driven by the same buffers.

3224. Refinishing Polished Aluminum Surfaces...??

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-10-20 16:46:07 UTC
From: slseto@aol.com
Message-ID: <20021020124607.02521.00002923@mb-ct.aol.com>
Source record: 40587

This note is about repairing a stereo turntable, but I was hoping that someone on this newsgroup might know about this particular problem...

I am looking at restoring a late-80's technics turntable, an old SP-10. The motor deck, which is a soft aluminum, has some ding's that look like they could be sanded down (with proper care, of course) so that they would at least have a minimal appearance. However, I'm uncertain if that might cause a worse problem.

For years, I THOUGHT that most natural-finished aluminum surfaces on Japanese equipment was clearcoated. (maybe soft anodized if coloring was involved...) That seemed logical because untreated aluminum likes to oxidize, and I've seen plenty of that. Recently, however, I've begun to wonder about this, based on some of the damaged aluminum surfaces that I've seen on vintage 70's and 80's equipment. If there WAS a clearcoat, where's the oxidation that should be present on older damaged surfaces? In the damaged areas, most are still quite shiny...???

Does anyone know about this? Has anyone had any experience refinishing these aluminum surfaces? Please contact me at the e-mail address above.

Thanks.

I suppose the sales margin for many items are too low to pay for the stockage. Contributing factors to this are the move of technology to SMT components and the 'dumbing down of ham radio'. Accompanied with the move to SMT is the fact that very few electronic end items are sold with schematics these days.

For instance a couple years back I purchased a cute little "circuit board video camera" which subsequently got zapped by a lightning spike. The dealer didn't have (or want to be bothered with getting) a schematic of the unit. This is a multi-layer board with incredibly small SMT components. I've determined that video is present close to the output connector but for the life of me I haven't been able to locate the little speck which should presumably be an open coupling capacitor.

Sorry for the poor description. It is all I received via email from a
ham that told me this unit contained the
2c39a tube. The bottom line is that I am trying to find a filament
connector for the 2c39 to complete an amp.
for 1296 mhz. I had hoped to strip one out of said unit.
So, I am trying to find that connector, not any Motorola
unit in particular. BTW, I have no idea what this connector looks like.
Thanks, Jim, K8JL in Mi.

Sounds like a base station transmitter. A 2C39 socket should be
obtainable at a hamfest or in one of the ham surplus places.

I've started to use a program simply called PCB. Its freeware -- don't have the URL for it handy but Google should give it to you. The latest version (IIRC) is 1.6.3.

It can do 2 sided boards as well as silkscreens. The library of parts that comes with it is mostly IC's [DIPs and SM's] and generic RLC's but you can create your own library parts.

It seems relatively easy to use -- I have been playing around with it a little and have generated some test artwork. It gives a an output in Postscript that you can print or in Gerber that you can have photoplotted.

You need a surplus T44. That is a tube-type 450 MHz transceiver that
was introduced by Motorola in the early 1950's and went out of
production in the early 60's. It uses two 2C39/3CX100 tubes. One for a
tripler/driver and one for a final. Both are in a rectangular cavity
structure and you can salvage the tube socket.

You should be able to find one for the taking. The key is knowing what
you are looking for. T44GGV was the mobile designation.

Well, I was considering G3YMC's approach using a loop antenna, this
requires 2500pF capacitors. But I am now told that the loop isn't as
good as I thought for a few days.

My intention was to learn which components were available and consider
the technical solutions then. Ground is a problem when you see only
rock around you, but a loop would have to hang E-W and would have a
zero to south, so I could possibly only work OH, SM and UA-stations.
Following Paul OH3LWR's and Roy W7EL's notes (further down the thread)
it is an interesting variometer described by IN3OTD at his site.

I am very lucky to live in Bristol, TN, home of Shields Electronics. Shields is, literally, a mom-and-pop operation -- although now it's run by the son. They have stores in Bristol, Knoxville, and Chattanooga.

Most of their sales are to commercial folks -- huge spools of wire and cable, connectors by the case, and the like. However, they committed long ago to keeping a stock of small parts -- transistors, diodes, ICs; full stock of resistors from 1/4 watt to 10 watt; toroid cores; printed circuit board; ceramic, mica, poly, and tantalum capacitors; potentiometers of every value and design; aluminum boxes, cases, panels; hook-up wire; Shields is like lots of places used to be. Don't know how long they can keep it up -- visit their website and if you are within range, visit.

http://www.shieldselectronics.com/ Look at the left side of the screen and click on Shields History.

A 2C39A has the outline of an "inverted lighthouse." No pins
whatsoever on the envelope. Filament connection is via
concentric cylinders at the narrow end. Cooling fins integral on
the wide plate end. Grid connection is essentially a flat disk.

Most "sockets" for the 2C39 are small finger-stock contacts
integral with the tuning cavity structures for L-band. If no good
metal-working machinery available it is best to use an already-
machined tuning structure with built-in contacts.

I think these could be Telefunken devices, they are in some AWA 1800 mhZ equipment built in early-mid 90's probably in Australia. They are power devices mounted, considerably larger than SOT-23 packege. Ceramic header is about 6mm dia, on metal base about 6 mm x 20 mm and fastened with two screws.

Hi Mike,

I think you have some old PHI transistors there. PHI is short for Power Hybrids, Inc. who was bought by M/A-COM years ago. MA/COM was bought by AMP (the connector company) and a few years back, Amp was bought by the giant Tyco, Inc. So if you can follow all that, you're better than most. They are still in Torrence, CA and their URL is:

http://www.macom.com/

Maybe someone there has an old catalog that would have the info on the devices you have. I used to keep a LOT of those old catalogs around, but with the internet so handy, bound catalogs are getting to be a thing of the past.

Hope this gets you a little closer to what you a looking for.

Mike G.

I've used the blue PnP stuff occasionally, or just shiny paper put through
the printer. Results aren't bad, but it doesn't take me any longer to make
PCBs with positive resist board and UV exposure, printing the artwork onto
tracing paper or special film. The results are very much better, also, and I
can re-use the artwork.

If anyone does know where this can be downloaded, I'd love to know. I spent a long time searching for it, to no avail. Google seems to only turn up Eastern European sites that give you passwords to open up the 3 or 4 disc set, mixed in with a lot of Porn links. Not a lot of interest or use. I have a 1 disc version of it that has no help files or libraries, but enough to be able to tell that it is a very useful tool for Ham use. I think it was originated by Protel, who no longer supply or support it.

Don't think it was a Protel product. AFAIK their first effort was
EasyTrax (later EasyFree when they gave it away) and then AutoTrax
(now also free). these were DOS products and followed by the (not
free) Protel for Windows range.

Many here in Australia use EasyTrax and AutoTrax for medium level
professional layout. I do.

From: Dennis <dont@spam.me>
Message-ID: <VQUs9.10198$DP6.33712@news-server.bigpond.net.au>
Source record: 40463
Cross-posted to: aus.electronics,rec.radio.amateur,rec.radio.amateur.homebrew,sci.electronics.basics,sci.electronics.repair

I've used "press n peel" quit a few times over the last year, the last time being about half an hour ago. In general I've found it to be effective and fairly simple, but limited to a fairly high track size. I've used it mostly for making audio amplifier PCBs which I use large/huge tracks on anyway so that limitation doesn't bother me. The smallest track I'd probably use would be about 20mil, but I usually use at least 40mil.

The most difficult part is the actual ironing onto the PCB. If it doesn't go to well there may be small breaks in a track, half a pad missing here and there, or if the plastic shifts slightly when you're first starting some tracks may end up with a smeared appearance, and end up wider than desired. Many of these defects can be corrected before you etch by using a permanent pen to cover over/replace any missing mask, or by scratching off any excess with a knife/scriber. Most boards I make will need about 1 minute with a pen to check and fix any small defects, but I rarely have to scratch anything off.

Before I first used the "press n peel" I came across a web site of tips on it (I no langer have the address). The two tips that I've found to be most helpful are:

1) Don't actually feed a whole sheet of the stuff into the printer. First print on plane paper exactly what you want to print onto the "P n P" noteing which way up the paper was in the tray it came from, and the direction the paper was fed through the printer. I usually use the straight feed paper tray that folds down on the front of the printer, not one the actual paper tray draws, and I draw an arrow somewhere on the paper to show the feed direction before it is printed on. You then cut a piece of the press n peel large enough to cover the image on the paper with maybe 1 cm overhang on all edges. With some sticky tape, tape down the leading edge (as it will feed through the printer) of the "P n P" directly over the image on the paper. Then put the paper back in the tray in the same orientation as before and reprint. You should end up with the paper being drawn into the printer, taking the small cutout piece of "P n P" smoothly in with it, in exactly the right spot for the image to be printed on it. Then take the "P n P" off the paper and iron it onto your clean blank PCB. By doing this you use far less of the "P n P" than if you used a whole sheet every time (unless you're making A4 sized PCBs). I'd generally get between 4 and 6 PCBs per sheet, so of the original 5 sheets I've got 2 left after making about 15 PCBs.

I've never had problems with the sticky tape going through the printer, but I can't make any promises about your tape going through your printer. (I wouldn't realy expect any difference, this is just a simple word of caution about the quality of tape you feed through your printer)

2) When you iron the "P n P" onto the PCB the corners will tend to curl up a bit, which will result in the tracks nearest the corners barely sticking down and not leaving the toner behind. So when laying out your PCB put a nice big fat (300mil) border around your layout to help stick the "P n P" in place when you iron it on and keep it nice and flat near the tracks you want to keep.

I would assume that not everyone would be happy with the quality of the results from "Press n Peel" but I'll continue to use it happily (until I finish the last 2 sheets then I might try something new so I have something to compare it to) as I was very quickly able to make PCBs adequate to my purposes with minimal initial cost outlay.

I hope this is of help.

Cheers

Dennis

Eagle is ace, though its a pig when you first start as the
docs are rubbish, I didn't bother with the circuit conversion
though it is very clever, I've just finished an smd board for
ctcss encoder/decoder using an fx355 chip, I like being
able to print out x2 as well
The componant library is extensive, and the freebie is
FULLY working, just a limit on the board size, not like
these other cripples floating around...

I've also used PNP with good results. Forget doing 10 mil traces...they peel off
but you can easily do SOT23, SO8, and SOT323 transistors.

The PCB --has--- to be clean. No grunge or tarnish. Use a green pad if you must
but avoid scrubbing compounds if you want to tin plate later...(as they hv
elements that tie up the tin in the plating solution.) And, the iron must be
HOT...but not so hot to melt the backing. Make certain there are no dirt "bumps"
on the PNP or PCB before you iron on.

Peeling back can become an art in iteself....do it slowly. Create a few "throw
away" board to practice.

Etching... what kind of etchant are you using?

Thanks for responding. I am familar with the tube and its
construction. I am under the impression that there is
a filament/cathode connector that has a portion that inserts into the
inner cylinder and a spring loaded
(finger stock) piece that surrounds the exterior of the outer cylinder.
This connector is a loose piece and not part of any particular assembly.
I have a complete
metal working machine shop and could concoct something if it comes to
that. My cavity and tuning structure are complete. Thanks, Jim.

It seems like a simple circuit using a microwave Schottky diode as a
rectifier should do the trick. You'd want to keep leads vanishingly
short. I can recommend especially Schottky "zero-bias detector
diodes" for this application, so long as you don't try to measure very
high voltages with them. They are capable of detecting signals down
well below a millivolt if you are careful about the readout part. You
need to be able to "see" down to the microvolt level of DC output.
And they typically have _very_ low breakdown voltages, on the order of
a volt, so avoid connecting to a point with high RF voltage. At low
signal levels, the output _voltage_ is proportional to input _power_
(input volts-squared).

The Agilent HSMS-2850 series of diodes is an example of a zero-bias
detector. You should be able to find the data sheet on Agilent's web
site, and I believe there's an ap note there too. The circuit can be
as simple as a capacitor (100pF or so) from the signal source to the
diode, other end of diode grounded, and junction of the diode and cap
fed to an RF filter (e.g., appropriate RF choke in series, 1000pF
shunt to ground after the RFC.), and then to a DC volt meter (DVM).
The diode's 0.18pF capacitance is helpful in avoiding loading of your
circuit. If you can keep things "clean" enough to limit the total
capacitance to, say, 0.25pF, that's close to 500 ohms impedance at
your op freq, and you can effectively make that a larger impedance by
using the RFC to broadly resonate the diode and stray capacitance. Of
course, at that freq., you'll need to keep leads to the point you're
testing extremely short as well. If you're testing a 50-ohm output,
then you can build it with a 50-ohm load on the end of a piece of
line, detector connected to the 50-ohm load. (It seems like, at 20mV
signal level, you must be at a low-impedance point.) It would be a
good idea to calibrate it with a known source!

Cheers,
Tom

Hmmm. Let me think.

I would guess that it would have to be a really old cell phone, like
maybe a 'bag phone'?

I used to work for AirTouch Cellular, before they became Verizon
Wireless. I've never seen inside a bag phone, but am guessing what it
would look like by comparing it to similar vintage equipment (and by a
guestimate based on its outside dimensions).

When I was working for AirTouch, they still had some of their 'first
generation' AMPS base stations built by GE, if I recall (or was it
Nortel?).

Anyway, these things would be relatively easy to convert. There was a
seperate receive and transmit module using parts you could actually
see (no surface mount!). The controller was an 8085 microprocessor on
its own board. They occupied about 8 inches of rack space per channel
(and a cell site might have 30-40 channels!). If you could figure out
how to control the PLL's, the RF boards would be easy to convert.
Several years ago I saw these things available surplus.

So my guestimate would be that anything older than 15 years, yes.
Newer than that would be difficult. As for how to do it, I can't say
myself.

Keep in mind that AMPS used wider bandwidths than Hams typically used.
Channel spacing is 30 kHz, and deviation was 20 kHz wide, IIRC. That
could be a problem for you.

Dennis

Many thanks for your detailed reply. I have to say that it sounds as if I'd be better off sticking to my current method of printing positives onto overhead-transparency material in my laser printer and using pre-sensitised PCB material. I do both analog (RF) and digital, usually on the same PCB, with track widths going down to 12mils.

Steve

My Google search turned up:

http://bach.ece.jhu.edu/~haceaton/pcb PCB freeware. This is *NIX
software that will only run with Linus, etc.

http://www.expresspcb.com ExpressPCB freeware, for Windows.

I haven't looked at the other results, but try searching using PCB rather
than pcb (i.e. use capitals not lower case).

I have had a close professional and personal relationship with my local Rat Shack for about 10 years now and they stopped carrying 1N34s long before 911. You could still get them until the your local store was out of them (And considering how few packs they were selling they lasted a long time, I was able to buy the last pack at my local store almost a year after they stopped carrying them.) but after the stock was gone that was it, no more. It has nothing to do with 911 or radioactivity (which 1N34s are not, although like most elements there are radioactive germanium isotopes) and more to do with the fact that no one except us homebrewers, who seem to be a dying breed, buy them. I design embedded controllers for a living and in 15 years as a designer I have yet to spec in a germanium diode.

My local store also recently went to the bin storage method to make room for the more "important" items. It makes shopping a lot more difficult since I used to go in and browse, now I have to open drawer after drawer to find what I want. I ran into a fellow who a few years ago was my local store manager and is now the regional manager and ask him why I could no longer get a 2N2955 and he told me that Rat Shack was going to continue to sell the higher volume small pieces but would no longer support the catalogue ordering that they have been experimenting with over the last 2 years and that they would be cutting back on the low sales volume, small piece items. When I asked him about the crappy drawer system he said that the small items would be packaged in smaller packages to fit in the drawers but the drawers where here to stay.

Didn't we have this discussion about 2 years ago? I could swear that the reason I bought the last of the 1N34s from my local Rat Shack is because there was a thread on this NG about the fact that the few manufacturers of germanium diodes had stopped production because of low sales and germanium diodes would no longer be available.

The _Handbook of Chemistry and Physics_ (59th Ed.) lists 13 different radioactive isotopes of germanium. None occur naturally.

You may wish to try a pair of high speed CMOS switches feeding a long-tailed pair on the back end after you find the proper PLL.

That sounds like the best option to me. With the lower track widths and track spacing you'd be much more likely to get track breaks and bridges. You might be able to use it successfully, but I'd guess that it would be unreliable, and if you've already got a method that works I'd stick with it.

Cheers

Dennis

Not quite sure what you mean? you have the option
of printing larger? though to print smaller would be
pointless as even with a really good printer you can't
get a good clear print on smd devices in real size.
you do have an enlargement facility when you are
drawing the board of course on screen so to speak
There are lots of options for downloading your design
to various pcb making equipment such as these new
cutting systems but beyond my pocket I'm afraid..

>
That's the point. Except for a handful of applications, nobody is
using germanium diodes anymore. 40 years ago, they were common, because
germanium semiconductors were more prominent than silicon. Once the
latter took over, the only reason for using germanium diodes was when
you needed the low forward voltage drop. Even then, schottky diodes
have taken over some of the uses that germanium diodes were used for,
and there are probably good reasons to use them instead of germanium.

I keep saying that when someone sees "1N34" most of the time someone
is specifying a generic germanium small signal diode (or more
specifically, a diode with a small forward voltage drop), so pretty
much any small signal germanium diode will work. The number was
specificied because it was being specified, meaning that the suppliers
would all stock something that they labelled that. If someone isn't
finding a "1N34" they may have problems finding a germanium diode,
because any germanium diodes may require tracking down.

Places that deal with the sort of people who do want germanium diodes,
ie people building "crystal radios", are likely to be the places where
one can get one. There isn't reason for the average supplier to stock
the thing, because who needs them?

In another newsgroup, brought on by the periodic "where can I get a 1N34
diode?" thread, someone pointed out the odd package of a real 1N34. I'm
not sure if I'm picturing it right, but I do remember noticing a
distinctive package years ago when I had some diodes that were definitely
germanium. With that in mind, during some recent circuit board stripping,
I pulled off some germanium diodes. Certainly those thirty year old AM/FM
radio boards (they were used in the am and fm detectors, but also in the
FM IF strip, presumably for limiting purposes) had germanium diodes. Cost
and age help to define them. But I found some diodes of the same sort of

package in some older cellphones (and I thought something else). The latter may not be germanium, their presence does seem odd, but they did have a lower voltage drop.

One can differentiate diodes with lower voltage drop from the common silicon diodes. Use a DVM with a diode function, and the silicon diodes will have a higher reading. Some small signal silicon diodes I just pulled out at random read .550 on my meter, while the ones I've defined as germanium read .2 to .250. Germanium diodes will also have a lower resistance in the reverse bias position from silicon diodes.

Obviously the older the scrap equipment, the more likely one will find germanium diodes. I have a stock pulled off scrap logic boards from about thirty years ago. Those cellphone ones are a mystery at the moment; if they are schottky (I don't have any known schottky to compare them with), at least they have a lower forward voltage drop than the common silicon diode.

Old UHF tuners are also a place for germanium diodes. The transistor ones (with continuous tuning), used a simple diode mixer, and those were germanium; at least some I pulled out recently had a lower forward voltage drop.

Someone might also use a base-emitter junction of a germanium diode. I'm not sure those would be any more available than a germanium diode, but at least this is an alternative.

It would probably be a 'good thing' for a hobby mag (or an advocate) to
design a simple 'crystal radio' with an inexpensive schottky. I'd think
that a schottky would work just as well, and a special schottky could
do significantly better???

All you have to do is enter "1n34" in an Internet search engine and you'll end up with several places that sell them. Dan's small parts is one that pops up.

I don't know about the Bristol store, but they charge an arm and a leg for parts here in Knoxville. There is a long-running joke amongst some of us in the commercial biz that you cannot shop there unless someone else is paying. Nowadays I try to mail order just about all my parts. By getting together a large order, you can save some pretty good money. Hamfests are also a nice place to get parts, although they are getting pretty scarce there as well. It may sound morbid, but if you run across a silent key's estate, you can usually get the junkbox for free if you will haul it off. The hams helping sell the equipment usually concentrate on the gear and don't know enough about the parts to want to bother with them.

Its hardly a design consideration but it has been shown that many diodes
are 'better' than the trusty ole 1N34. When discussions like this go
on, I wonder if the term "1N34" hasn't entered the lexicon as the
generic crystal radio diode that now is intended to be substituted with
your diode/razor blade of choice?

The model I have is an Air-Vac DVM4ESS Vacuum module. On the side it says that the "vacuum transducer pump" produces 28" Hg. Internally, there are filters and a solenoid/valve/etc. that produces vacuum when high pressure is applied. The valve is opened and closed by a foot pedal.

There's some good examples of low-level diode detectors at

http://engphys.mcmaster.ca/~elmer101/

See the articles on square law detectors at

http://engphys.mcmaster.ca/~elmer101/sqlaw/sqlaw.html
http://engphys.mcmaster.ca/~elmer101/sqlaw/sqlplots.html

Follow Tom Bruhn's excellent advice on short leads and signal levels, and
you should get good results!

Mike

W4PQW
================
A useful pressure below that of atmospheric pressure (vacuum if you wish)
can be created by means of a venturi tube , basically a piece of pipe with a
(narrow) throat .
When blowing air through the venturi tube ,due to increase of air velocity
in the throat the static pressure will drop.

In laboratories a well known venturi type vacuum device is connected to a
water tap . With the water drained or collected at atmospheric pressure ,the
under-pressure (vacuum) which exists at the throat connection can be set by
adjusting the water flowrate.

If such a device would be used for desoldering ,one would probably have to
fit an intermediate enclosed pot with a dip pipe to almost the bottom . With
the dip pipe externally connected to the solder sucker and the venturi
device vacuum connection connected to the top of the pot , any solder would
be left inside the pot rather then clogging the venturi vacuum device.

Perhaps someone on this NG could locate a source for such a 'vacuum' device
to assist potential users.

Just as a heads up, many of the venturi type vacuum generators can be
noisy in operation. Usually not a problem in a lab or production
facility, but could be in a home situation. Give it a listen before
buying, if you can.

Pace makes a compressed air vacuum desoldering unit. They are commonly used in plants.
They are cheaper than the units that have individual vacuum pumps in them.
They have all the same components in them that a regular Pace unit has except that instead of a
vacuum pump there is the compressed air vacuum generator.

Message-ID: <FB3639F275CA9379.055C3188FF6E0ACE.4F7042862919DCD4@lp.airnews.net>
Source record: 40378

I would like to build my own multiband antenna. I have about 30 feet of 1" aluminum tubing. I would like the antenna to function from 10m to 80m if possible. I can go approximately 30 horizontally or vertically due to space/neighbors restrictions. My questions are as follows.

I would like the setup that gives me the most rf out best receiving of course.

If I build a vertical, would it be best to mount it around 10' off the ground with limited radials around 6', or ground level with radials running a little longer maybe 12'-15'. What about with no radials at all?

Is a tapped coil at the base hand switched better than traps, or would it be best to just make the antenna one long piece of aluminum with no coil? I know the last method requires an antenna tuner but what about the tapped coil method and trap method?

Is there a difference between an antenna tuner in line with a plain vertical, and a vertical tapped with no antenna tuner, other than the fact that the antenna tuner would provide wider coverage?

What about a 30' dipole about 10' off the ground, or a beverage?

Sorry I know these questions are basic, but I've been reading up online and I haven't figured out all the basics yet. I'm space restricted and to some extent height restricted although a single pole sticking up wouldn't be a problem.

Thanks
Robert

I've used it with mediocre results. As others have said, it's good for big stuff, but forget anything surface mount. (I prefer surface mount, as then you don't need to drill all those holes... <G>)

Honestly, I really prefer to use the presensitized PCB method. You don't need a darkroom to do it; I work on the bathroom counter with the bathroom lights off and the hall lights on. I've done surface mount as fine as 0.5mm (20 mil) pitch; that takes some care and strict attention to timing. (Haven't had to do anything finer.)

The only extra steps involved are exposing the board and developing the exposure. Everything else is the same.

3296. New program OSCTRACK.exe

Source record: 40508

NOW AVAILABLE ** New Program "OSCTRACK.exe"

Tracking of RF signal and local oscillator tuned circuits in superhet radio receivers.

The program calculates all L and C component values and then checks tracking error as the two-(or more)-gang tuning capacitor is varied from the keyboard from one end of the band to the other. Covers all signal frequencies from VLF to UHF for any Intermediate Frequency (IF).

Ideal for receiver home-brewers.

Download in a few seconds from website below and run immediately.

> Does anyone still design this type of radio?
==========
Yeah, there hasn't been a TRF receiver made and sold for the last 60 years.
Well before you were born.

Supersonic Heterodyne receivers rule the roost. Some have two, even three
intermediate frequencies.

There's been a tendency lately to sell the RF preselector as an add-on extra
which loses much of the operating convenience.

In comparison with the complete version a receiver without a preselector is
a load of junk.

Larry,

I would suggest to try Linear Technology RF Power Detector IC,
LTC5505-1 or LTC5505-2 :

http://www.linear-tech.com/

You can also buy these ICs from Digi-Key:
http://www.digikey.com/scripts/us/dksus.dll?Detail?Ref=68342&Row=217504

The LTC5505-1 and LTC5505-2 are RF Power detectors for frequencies 300
to 3000 MHz. 5-pin SOT-23 package. Very easy to use.

==========

Mick and others,

Get a reel of some 20 or 18 or 16 gauge enamelled copper wire, two or three empty toilet or kitchen roll tubes, plus a 35mm film container, a dozen small crocodile or alligator clips on the ends of a few inches of flexible stranded plastic-insulated wires, and two 350 or 500 pF receiving-type tuning condensers with knobs on the ends of the shafts. Capacitor vanes should not be too closely spaced.

Wind two or three close-wound coils One with about 40 or 50 turns. Another with around 10 or 15 turns. Leave three or four small loops in the turns to allow coil tapping. You can also wind two close-coupled coils with different numbers of turns on the same former.

The fewer the number of turns the higher the frequency bands.

You should then be in a position to match almost anything to anything using an L-network. If that occasionally fails then try a T-network. Always try the most simple circuits first - just a coil or a capacitor in series or in shunt with the antenna.

It is impossible for circuits to become complicated. At most, in any matching network, there are only 2 or 3, L and C components.

You can get something working much sooner than shopping around with a cheque book, one grasping dealer after another, searching for a black box it is very likely you will not be satisfied with because the coil doesn't have the right number of turns.

I often leave the bits and pieces on the window ledge to greet the antenna wire as it comes indoors through the window. Any sort of gap or slot or tiny hole in the window will do fine. If its through the kitchen window then you will find an excellent convenient ground connection via a jumbo clip on the domestic plumbing. Prefer a cold water pipe because it's nearer to the incoming main.. The ground is as important as the aerial wire.

Draw your own free-hand circuits with pencil and paper. Keep a record. It helps to remember long after you have mislaid them.

If you don't dislike using numbers, get an idea of what to expect with simple aerial wires by using easy-to-use program ENDFEED. Download in a few

seconds and run immediately. You won't need a college training course of instruction.

The foregoing is thoroughly recommended even if you have won the Irish Sweep and are rich enough to buy an all-singing, all dancing, bells and whistles black box with knobs on.

I have never had a commercial tuner nor ever run out of coil formers or enamelled copper wire in 60 years.

Enjoy yourself !

In one of the older QST handbooks, or other ARRL publication, was an article on building a DSB demodulator that required both sidebands present, and would reject off-frequency QRM very well.

Now I have a CE100V and would like to play with the circuit, but I can't remember where I saw it. Anybody have any reccolection of that, and knows where to find it???

Your assistance would be greatly appreciated. Please replay directly on e-mail.

You might also check out Analog Devices' offerings for RF power and RF logarithmic amplifier-detectors.

Also, further to the simple diode detector ideas...although I (and someone else) recommended "zero-bias detector diodes," you can for sure use other diodes. Germanium junction and point-contact diodes and Schottky signal diodes not specifically intended for zero-bias work are all candidates.

Cheers,
Tom

3315. Heathkit GR-78 Battery

I'm restoring a GR-78. Fortunatly someone removed the battery years ago. I know the original battery was a NiCad (I plan to use one too). I can also tell the battery is "split" in other words charged as two batteries, then used as one battery. Does anyone know how many cells this battery has? A first guess looks like 4 cells on each side. In other words an 8 cell / 10 Volt battery. This sounds odd so I thought I would ask if anyone knows for sure.

Thanks,
Gary

As an alternate for small workshop use at home, I'd suggest any sort of reciprocating vacuum source. A used airbrush compressor works fine, doesn't pull a great vacuum and is not overly loud.

One problem is trapping solder balls and other detrious picked up from the work. A plastic Skippy peanut butter jar is fairly sturdy as a garbage trap for mild vacuums. One between the work hose and the connection to the vacuum pump can have stiff plastic connections through the peanut butter jar lid (use plenty cement) and the jar itself can unscrew easily for cleaning.

Some jam and preserve jars have stiff, sturdy bodies as physically good as the Skippy peanut butter containers.

The Analog Devices logarithmic ICs would be excellent as 40 to 80 db dynamic range signal indicators. One could make a low-level power meter for CW signals reading out directly in dbm by adding a panel DVM coupled with an op-amp or two. Putting a FET source follower ahead of such a log amp chip would make it a relatively higher-Z probe for old-fashioned signal tracing. A lower frequency output 80 db range IC can be the heart of a spectrum analyzer for a very linear vertical-scale power level indication. It would seem prudent to invest once in slightly more monies and wind up with a lot more measurement capability.

The problem with any such device is just calibration. Without a known-level RF source to check it out, using one would be just guesswork or a something-nothing indicator.

Reg, you do some nice programs but I have to take some issue with
some of your statements quoted above.

To clarify, a "preselector" in a receiver is some form of bandpass
filtering ahead of the first mixer in a superheterodyne. Given a fairly
common loaded Q of about 40 in a 20m receiver's "preselector,"
the bandpass is roughly 355 KHz for a single-tuned circuit. A two
or three-resonator narrow fixed-tuned bandpass filter can cover a
full 400 KHz bandwidth without problem...and still present enough
skirt selectivity to handle all images as well as any gang-tuned
variable preselector.

Case in point: A Heath SB-310 SW/ham band HF receiver, a variant
of Heath's "SB" series ham receivers designed two decades ago.
The 1st LO is crystal controlled and 8.9 MHz higher than the
selected band's lower edge. The 1st IF is a bandpass filter of about
8.9 to 8.4 MHz. The 2nd LO is variable (the tuning) of 5.5 to 5.0
MHz, linear frequency change, with 2nd IF crystal filtered at about
3.4 MHz center. The image frequency of the 1st IF is 15.9 to 16.4
MHz on the 80m band, far outside any preselector tuned circuits'
response.

The original preselector system was a separate two-gang variable,
each section resonating at the same frequency. This was a PIB
to change after every band change. It was a simple matter to
simply fix-tune the capacitances in the preselector and tune each
band as a staggered-double according to Wallman's chart in the
old MIT Rad Lab books. Except for the 80m band, all other bands
were narrow enough to accept that slight modification without

problem; 80m band was centered on the 'phone portion instead of
the whole band. Far-from-resonance response was still as low as
it was originally (measured with an H-P 606 signal generator).

Ed Armstrong's original 1918 superheterodyne patent described
down-conversion to achieve a constant bandwidth via the IF. That
was fine in 1918 or 1920 (when that patent was granted) when
there were no crystal filters for the IF and crystals for LOs were
very expensive. But, UP-conversion in a first mixer is quite viable
to a higher IF with the first LO crystal controlled. The high 1st IF
can easily be made a fixed-tuned narrow bandpass filter and the
actual tuning done in a variable-frequency 2nd LO. No ganging
of tuning capacitors is required. All receiver tuning is done solely
by the 2nd LO frequency. All other tuning is physically fixed
except by 1st LO crystal and antenna-1st Mixer BPFs selected
for a particular band.

For non-superheterodyne receivers capable of either CW or SSB
reception, I'll point to the so-called "DC" aka "direct conversion"
aka "zero-IF" type. In that version the LO is at the received
frequency. One could make one with only the LO tuneable or
have it track the antenna-RF tuned circuits with no offset. No
tracking problems at all with equal-section tuning caps. :-)

There was considerable work done in Europe on "zero-IF"
receivers a quarter century ago as witness several articles in
RSGB's "Radio Communicaiton" magazine, particularly Pat
Hawker's columns.

>Yes.

Incorrect as of about a half century. The "two-point" or "three-point"
tracking problem-solution of single-band (generally the AM BC band)
receivers was required when ganged variable capacitors had equal
capacitance values per section or "gang." In the late 1940s the
common AM BC band receiver had been designed with two-gang
variables having unequal sections. Further, the capacitance change
of the smaller-capacity section (for the LO) could be cut to fit
the resonance frequency of the "antenna" circuit (at the desired
input tuning frequency). This was done until the 1980s and included
the tiny 2-gang plastic film insulated variable tuning capacitors of
Asian design and manufacture.

This "tracking problem" of the RF input versus the LO frequencies
really went away with up-conversion of the first mixer in relatively-
narrow band receivers to a high first IF. The first mixer (and RF
amplifier) could be fixed-tuned as bandpass filters...Q of inductors
at the common HF ham bands resulted in no need to gang-tune
the "preselector" ahead of the first mixer with any LO. Actual
tuning was done in the 2nd LO. The 1st LO could be crystal-
controlled on each band. The Collins Radio 51J series of
receivers did this in 1950 (US military R-388) and this was also
done with the same-era "390 series" military receivers. The
Heath SB series receivers did this a decade-plus later. All of
the modern (designed, built in last three decades) HF receivers
use this architecture scheme. It lends itself well to "reversing
the RF flow" for a transceiver's transmit signal path.

Anyone would be hard-pressed to find ANY receiver for LF to UHF on any market target area that used equal-section ganged tuning capacitors in the last three decades.

>Old does not mean bad, useless or obsolete.

Neither does such a comment mean it is in any way useful to anyone designing/modifying something in relatively-new radio tuning.

The "three-point tracking" problem seems to have hung in texts on radio design from the 1930s on into the 1960s. It is a surprisingly complex mathematical solution to a seemingly-simple problem of adding "padding and trimming" capacitors (series and shunt caps) to a variable section. One reason it is complex is that frequency of resonance is a function of the square-root of capacitance (with fixed inductors). Mathematics of it have long since been worked out and may be easily solved in a small computer program.

What results is an easy-to-use solution for a no-longer-existing application in production receiver design...or at least a very, very rare application in modification of an old boatanchor style receiver circa 1950 or earlier.

I'm in complete agreement with Leonard. This is why RF is a pain in the
Democrat. I would guess, however, that the chip may be hard to get if not
available at Digi-Key and is probably expensive. Oh well! This is a

hobby!

>
It all depends upon the FET (as you already know!!!) However, one trick
(depending upon the situation) is to use some negative feedback. It
is often better to match a FET for noise (on a front end), and you can
sometimes push the load on the input closer to the noise match.

If you are really going to try to match the transistor from 50ohms
to S11 of 0.99, you'll likely have a narrow bandwidth circuit. If
the transistor has too high/low an impedance on input or output
(after appropriate load, stabilization resistors, etc), then a little
bit of local negative feedback can sometimes help.

If all you want to do is to push the input/output impedance
downwards, you aren't worrying much about reverse isolation, and
you have some excess gain, you can use the
good ole' feedback resistor/capacitor between gate and drain
on a common source circuit.

The feedback resistor (capacitor for DC block) will load the input and
affect the noise figure, but the decrease in input impedance
will be significantly greater (because of gain) than the resistance.
So, the noise figure will be increased essentially as if the
resistor is in parallel with the input, yet the input impedance
will likely be decreased significantly more, so as to get a
better return loss.

If you are interested in wideband at high frequencies (UHF/SHF),
then a series resistor/inductor combo for the parallel feedback
will sometimes be helpful.

If you need to push the input impedance upwards (for UHF or
higher) so as to come closer to a noise match, then a small
amount of source inductance can be helpful. The source
inductance will tend to reflect as an increased resistance in
the effective input impedance, without alot of noise added
like a real series resistance. You should be careful
with adding too much source inductance, because even though
it can improve stability at low microwave (e.g. 1GHz), it can

sometimes make a circuit less stable at 5GHz or higher.

Now, if you need for your FET to see a higher impedance (for a better noise match at lower frequencies), then you might need to compromise a little. For wideband, balun type transformers can help (perhaps 1:4), and then help to push the transistor towards the right impedance for the output of the transformer: 200ohms or 300ohms. For narrowband, there are more choices.

There are all kinds of ways to maximize return loss, with some negative feedback, transmission line techniques, and other schemes. It can sometimes be trivial, or multiple techniques can be used.

John

Thanks John. I guess I should have qualified the GaAs FET part as being a power part for up to 37 dbm. It is a whole different ball game and not in line with what I implied. Of course we have 4 fempto meters of room to add zero components to, in order to match an infinite loaded Q. I think I'll use a 2C39 tube and use cavities. :-). The only thing that could make this worse is if they required me to do it with a supply of 1V and a drain of 1 uA. Did you ever try to explain the laws of physics to a business major? I wish that I had stayed an astronomy major. I'd be popping tabs on my beers atop Kitt peak or in Hawaii running away from the erupting volancoe instead of getting ulsers from RF design. I'm burned out! I want to dig up Smith, slap his face and put him back in the ground for what he has done to me. (and I'm considered normal for an rf engineer, by many experts :-))
